## ABSTRACT

The Adaptive Architectures for Command and Control (A2C2) project is a four-year effort sponsored by the Office of Naval Research to explore adaptation in command and control structures. The project's first experiment involves studying interaction between task structure and organization structure. Although the organization structure dimension of interest was clear, not enough was known of the dimensions of task structure to determine the dimension of interest without further study. This thesis describes a process for developing military operational scenarios within a task structure context. First, the author conducts a literature review, defines the dimensions of task structure applicable to this project, develops a grading scale for each dimension, gives examples of the dimensions and grades each example, and describes how changes in one dimension might affect other dimensions. Then a method for developing scenarios in accordance with a predetermined structure and visualizing tasks is described, including a task structure diagram and a description of a task design process using the diagram and the dimensions previously delineated. The author then applies the task design process by developing two scenarios for the first A2C2 experiment that differ across one dimension of task structure, *coordination requirements*. Finally, a description of the experiment is given, including discussion of operationalization of the scenarios and organization structures, and lessons learned from the experiment with regard to scenario design.

## EXECUTIVE SUMMARY

The Adaptive Architectures for Command and Control (A2C2) project is a four-year effort, sponsored by the Office of Naval Research and conducted by researchers at the Naval Postgraduate School (NPS), Alphatech, Inc., the University of Connecticut, and several other institutions. The goal of the study is to explore how, why, and when organizations adapt or should adapt their structures and what skills, training, and technology are required to support that adaptation. The project itself will consist of field research and a series of experiments.

The first experiment was conducted at NPS in March 1996. The purpose of this initial experiment is to serve as a "baseline" for the experimental phase of the A2C2 project, and to study interaction between task structure and organization structure, in a 2x2 factorial experimental design. The organizational structure dimension of interest was clear from the overarching purpose of the A2C2 project and current emphasis in the Department of Defense and industry on "flattening" organizational structures: levels of hierarchy — does a flattened hierarchy perform tasks better under certain circumstances than a hierarchy with more levels? However, the task structure dimension of interest was less clear. Although there are several discussions in the literature of single dimensions of task structure, nowhere is there a comprehensive breakdown of the dimensions of task structure, including some way of quantifying or determining the levels of each of those dimensions so they can be held constant or varied in a situation where task structure is an independent variable. And, once these dimensions are defined and the dimension to be varied has been decided upon, how can a task be visually represented for ease of understanding and manipulation, and a military operational scenario be designed to fit into this task structure? This task design and scenario development process is the focus of this thesis.

The author begins by conducting a literature review, and defines the dimensions of task structure applicable to this project based on the literature and his own experience. These dimensions are *uncertainty, time pressure, complexity, coordination requirements,*

*magnitude, resources required, information required, task formalization, and dynamicity.* Then, a grading scale for each dimension is developed, examples of the dimensions are given and graded based on the previously developed scale, and the author describes how changes in one dimension might affect other dimensions.

Once the dimensions of task structure are defined and a grading scale developed, the author describes a task structure diagram, whose purpose is to visually represent the flow of activities within a task, possible paths, simultaneity constraints, competition over resources, prerequisites for activities, resources and information required for the performance of activities, decomposability of activities, and dynamicity, or the degree to which activities change over time, to experimental designers. Many of the dimensions of task structure previously described are represented directly in this diagram; others can be inferred from it. This visual method allows experimenters to more easily determine if a task accomplishes the objectives that have been set, and provides a straightforward, visual method for comparing it with other tasks and for describing a task to those outside the task design process. After the diagram has been developed, the author describes how the dimensions of task structure defined previously relate to the visual method. Then, the author describes a straightforward process for developing military operational scenarios when task structure is to be an independent variable. The steps in the process are to determine the task structure dimension of interest, determine desired task structure and levels of dimensions, develop the scenario, and grade the scenarios by dimensions.

The author then applies the task design process described above to the A2C2 initial experiment. The dimension of interest was determined by the definitions of dimensions of task structure given previously and initial A2C2 field research, where the question was repeatedly asked: when two units in the same functional area must compete over assets owned by one of them, does an intermediate level of hierarchy overseeing that functional area help, or is a flattened hierarchy better? And which organizational structure is better if the units are competing over assets owned outside their functional area? The dimension of interest, then, is *coordination requirements*, at two levels: high internal competition over shared resources and high external competition over shared resources.

The author begins with the scenario used for A2C2 field research and develops two scenarios at the joint task force (JTF) level that differ across the dimension of interest, and grades the scenarios based on the dimensions of task structure developed previously.

Finally, the author gives a description of the experiment, including setup, discussion of operationalization of the scenarios and organization structures, training conducted with the subjects, conduct of the experiment itself, and lessons learned from the experiment with regard to scenario design, in terms of the usefulness of the scenario design process described in this thesis and issues that must be taken into account in order to effectively design and implement a scenario that contains independent variables.

## **I. INTRODUCTION**

### **A. BACKGROUND**

In the effort to capitalize on the ongoing revolution in military affairs, a current area of focus within the Department of Defense is organization of the force. New, more highly evolved organizational concepts are considered one of the "enablers of the revolution in military affairs" (Joint Warfighting Center, 1995, p. 13). The Joint Staff's C4I for the Warrior (C4IFTW) concept, Copernicus, Sea Dragon, and other service initiatives that reside within the overarching C4IFTW concept call for flattened command structures. These flattened command structures would make more efficient use of enhanced sensor-to-shooter communications capabilities and the dominant battlespace knowledge that, it is hoped, U.S. forces are on the road to achieving as a result of the tremendous pace of technological advance and our leveraging of that technology. Further, it is posited that the most responsive and capable organizations will adapt their structures and processes from traditional, rigid hierarchical organizational structures into more flexible, network-like architectures in order to take advantage of the opportunities presented by the information age (Joint Warfighting Center, 1995, p. 18).

### **B. THE A2C2 PROJECT**

It was within this context that, in the summer of 1995, the Office of Naval Research (ONR) commissioned a four-year research project called Adaptive Architectures for Command and Control (A2C2). The A2C2 project is a joint effort of researchers at the Naval Postgraduate School (NPS), Alphatech, Inc., the University of Connecticut, and several other academic institutions. The project's goal is to advance the state of knowledge regarding decision making in organizational settings, to include an understanding of how, why, and when organizations adapt or should adapt and what skills, training, and technology are required to support that adaptation (Alphatech/UCONN/NPS, 1995, p. 2). The researchers will make use of theory, practical experiments, and field observation in order to gain this understanding. The A2C2 project

will move through several different phases, which began in late 1995 with visits to military organizations, participation in demonstrations and wargames, and a round of structured interviews with experienced commanders from all branches of the U.S. Armed Forces. The purpose of this field research was to identify drivers of adaptation in joint operations, from the perspective of those experienced in joint operations, and raise the specific issues that can and should be dealt with in the project's later experiments.

After the interviews, the A2C2 researchers have begun to conduct a series of experiments of gradually increasing complexity and fidelity. Each experiment will build upon the insights gained from modeling, the field research, and previous experiments, and will be conducted using wargame/simulators of complexity and fidelity commensurate with the experiment being conducted. This thesis involves the first of those experiments, which was conducted using the Distributed Dynamic Decisionmaking III (DDD-III) simulator, a relatively low-fidelity, high-abstraction tool, with officer students from NPS representing each branch of the service as subjects.

### **C. THE FIRST A2C2 EXPERIMENT**

The first experiment in the A2C2 project was conducted at NPS in March 1996. The purpose of this initial experiment was to serve as a "baseline" for the experimental phase of the A2C2 project. Objectives included: adapting the existing game simulator (DDD III) to the broader operational domain; examining organizational structure as an independent variable, and testing interaction between organizational structure and task structure; identifying current research issue(s) that are common to the operational and theoretical (from literature) domains, that can be examined within the context of the scenario used in the interviews; developing the scenario and tasks down to a level amenable to modeling analytically and in simulation; providing insight into wargame/simulator requirements for future experiments; and examining measures that may be useful for research into adaptable C2 architectures.

The first experiment was conducted at the intersection of a number of constraints. These included the field research that had been conducted, to include the joint officer interviews and field visits to exercises and warfighting commands; the pool of

experiment subjects at NPS; the requirement that any scenario developed be joint in its nature; the hardware available to conduct the experiment at NPS; the factors of interest to the A2C2 project; the requirement that the experiment be conducive to modeling and simulation; and the capabilities and limitations of DDD III.

Testing the organizational structure/task structure interaction was the driver of the experimental design. When testing this interaction, in order to isolate effects, it was desired that task structure and organizational structure be varied in only one dimension each, holding all others constant. This resulted in a  $2^2$  factorial design, with each factor held at two levels. The A2C2 team decided to use four six-person teams, composed of military officers from all four services with normally one or two operational tours behind them, conducting four trials per team in a balanced, full-factorial design with four data points in each task/organization structure combination.

The difficult question, then, is which dimensions of organizational structure and task structure should be varied? And, once that is decided, at what two levels should the dimensions be held? The overarching purpose of the A2C2 project and the current issues being addressed in Copernicus and C4IFTW suggested clearly that, in the case of organizational structure, the dimension of interest should be *levels of hierarchy*: is performance of an organization enhanced if one or more levels of hierarchy is removed (the "flattened" structure envisioned as superior in the technology-enhanced near future), particularly in an environment where there exists a common operational picture (COP) among all members of an organizational structure? The A2C2 team further decided that the two levels to be tested should be a two-tiered hierarchy and a three-tiered hierarchy (Figure 1). Task structure, though, was more difficult. While the literature on the subject of organizational structure is rich, plentiful, and well-developed, that regarding task structure is not. Although there are several discussions in the literature of single dimensions of task structure, such as complexity, uncertainty, or coordination requirements, nowhere is there a comprehensive breakdown of the dimensions of task structure, including some way of quantifying or determining the levels of each of those dimensions so they can be held constant or varied in a situation where task structure is an

independent variable. And, once the dimensions of task structure are defined, the dimension to be varied has been decided upon, and the structural form which the task will take has been determined, how can a military operational scenario be built to fit into this task structure? This task design and scenario development process is the focus of the thesis.

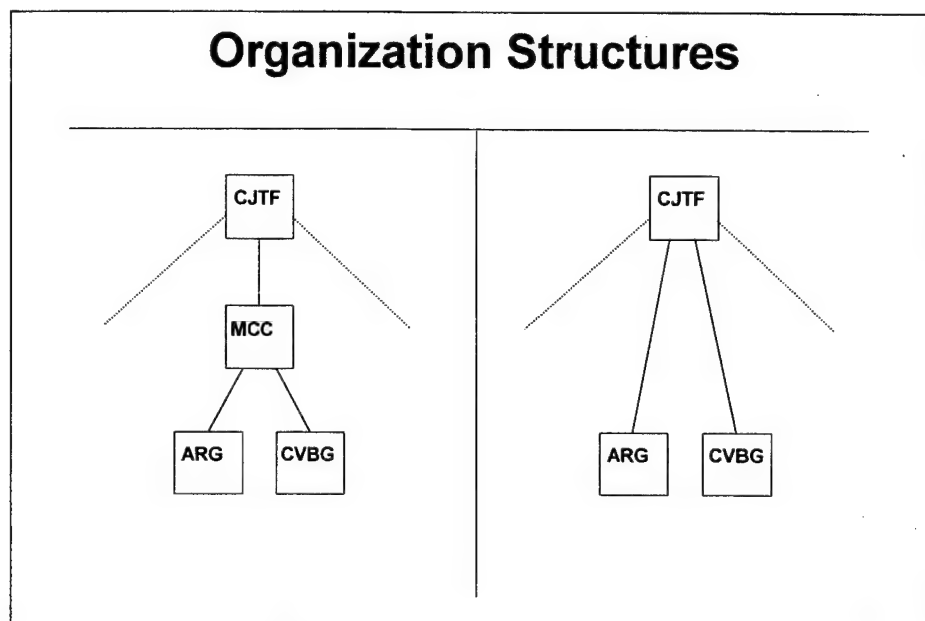

Figure 1. Two Organization Structures Used for First Experiment

#### **D. FOCUS OF THESIS**

The purpose of this thesis is to develop a process for developing military operational scenarios within a task structure context. As a starting point, I will perform a comprehensive literature review, define the dimensions of task structure, quantify those dimensions, and give examples of each dimension and quantifications of the examples (Chapter II). I will then develop a diagram to be used for developing scenarios in accordance with a predetermined structure, and correlate the dimensions of task structure that I define in Chapter II with the elements of the task structure diagram, and briefly outline a task design process based on the dimensions from Chapter II and the task structure diagram (Chapter III). I will subsequently develop two joint tactical scenarios written for the DDD simulator that differ across the dimension of task structure that the A2C2 experimental team decides is the most important one, and in conjunction with the

predetermined structure that the A2C2 team decides that it wants to use, utilizing the task design process from Chapter III. The results, analysis, and conclusions of the first A2C2 experiment are outside the scope of this thesis. However, I will describe the conduct of the experiment and operationalization of the scenarios and organization structures (Chapter IV). Finally, I will detail lessons learned from the experiment and application of the task design process as they pertain to scenario development and task design, and I will summarize the thesis (Chapter V).

## **II. DEFINING DIMENSIONS OF TASK STRUCTURE**

### **A. INTRODUCTION**

It is clear that, in order to successfully determine which types of organizations function best with different sorts of tasks, an organized and disciplined method with which to cause tasks to be different must exist. In order to cause tasks to be different, we must be able to differentiate between tasks. And, before we can differentiate between tasks, a task must be characterized. One way to characterize tasks is to decompose each task by the level of its various dimensions. What, though, are those dimensions of task structure? As mentioned in the previous chapter, there is little in the literature of organization theory and behavioral decision theory with regard to dimensions of task structure. Discussions of one or several dimensions of task structure are common (Wood, 1986, Campbell, 1988, Malone and Crowston, 1994, Ben Zur and Breznitz, 1981, Davis et al., 1991, Evaristo et al., 1995), but a comprehensive enumeration of these dimensions is lacking.

The purpose of this chapter is, first, to review the literature on the subject of task structure. Next, I will enumerate and define dimensions of task structure, based partly on the literature and partly on my professional experience, and develop a grading scale for each dimension. I will then give examples of tasks that clearly exhibit the dimension of interest, and grade each example given using the scale developed earlier. Finally, I will discuss the interaction between dimensions or the degree to which changing one dimension affects other dimensions.

### **B. LITERATURE REVIEW**

The literature on dimensions of task structure is mainly composed of articles and papers from technical journals. The works described below are the most significant to date from the perspective of enumerating dimensions of task structure. Six articles are discussed: Wood (1986) and Campbell (1988) deal with complexity, Malone and Crowston (1994) consider coordination requirements, Ben Zur and Breznitz (1981) deal

with time pressure, Evaristo et al. (1995) describe time pressure and uncertainty, and Davis et al. (1991) discuss task activities, time frame, task formalization, task ambiguity, task complexity (using Wood's (1986) definition), and task significance.

## **1. Wood**

Robert E. Wood, in his article, "Task Complexity: Definition of the Construct" (1986), first states that tasks contain three components: (1) the *product*, or what is produced by completing the task; (2) *acts*, or things that must be done in order to complete the task; and (3) *information cues*, or information that provides the stimulus for performance of a task, or is required for the task to be completed. He then defines task complexity in terms of these three task components, and decomposes task complexity into three different components: *component complexity*, *coordinative complexity*, and *dynamic complexity*, and discusses methods for quantifying each of the components.

### **a. Component Complexity**

Component complexity is a direct function of the number of distinct acts that must be completed in the performance of the task and the number of distinct information cues that must be processed in order to perform the acts. Wood gives the sum  $TC_1$ , the measure of component complexity, as the sum of information cues for all acts of all subtasks within the task.

### **b. Coordinative Complexity**

Coordinative complexity, as defined by Wood, refers to the relationships between task inputs and task products. It describes the form and strength of the relationships between information cues, acts, and products, as well as the sequencing of inputs. Wood gives a number of different indices with which to attempt to measure coordinative complexity, most of which are a bit obscure and difficult to obtain, and I will not elaborate on them because of the space that would require. The most straightforward is the sum of all precedence relations between each act and all other acts in the task, which he denotes  $TC_2$ .

**c.      *Dynamic Complexity***

Wood defines dynamic complexity as changes in the task environment which affect the relationships between task inputs and products. He measures this by summing the changes in  $TC_1$  and  $TC_2$  over discrete time periods, reduced by the change multiplied by a predictability coefficient for each time period, to arrive at a dynamic complexity figure denoted  $TC_3$ .

**d.      *Total Complexity***

To arrive at a figure for total complexity, Wood obtains a weighted sum of the  $TC_1$ ,  $TC_2$ , and  $TC_3$  totals. The specific weights, represented by coefficients, assigned to each sum would be situationally dependent, constrained by the requirement that  $TC_1$  be more heavily weighted than  $TC_2$ , and  $TC_2$  more heavily weighted than  $TC_3$ .

**2.      *Campbell***

Donald J. Campbell, in his article "Task Complexity: A Review and Analysis" (1988), took a different approach to defining complexity. He posited that task complexity is closely related to information, and that any task attributes that increase the load, diversity, or rate of change of information should be considered contributors to task complexity. He found four task characteristics that meet that criterion: the degree to which a task contains *multiple paths*, *multiple outcomes*, *conflicting interdependence among paths*, and *uncertain or probabilistic linkages*.

**a.      *Multiple Paths***

Increasing the number of possible ways to complete a given task increases the complexity of the task. This is particularly true if the paths vary in their "goodness," that is, some paths more efficiently or effectively complete the task than others. Complexity is reduced if all paths presented are of equal goodness.

***b. Multiple Outcomes***

Outcomes are the different results the performer of the task wants to achieve when the task is completed. The greater the number of different outcomes, the more complex the task.

***c. Conflicting Interdependence Among Paths***

Campbell defines this as negative relationships among desired outcomes. If achieving one outcome conflicts with achieving another outcome, task complexity increases.

***d. Uncertain or Probabilistic Linkages***

Campbell defines linkages as the connection between potential path activities and desired task outcomes. If there is difficulty determining these linkages, or the linkages have a probability of less than one, information processing requirements are increased significantly, and task complexity increases.

**3. Malone and Crowston**

Thomas W. Malone and Kevin Crowston, in their paper "The Interdisciplinary Study of Coordination" (1994) define coordination as managing dependencies between activities. They defined four different types of dependencies that could need to be managed: *shared resources*, *producer/consumer relationships*, *simultaneity constraints*, and *task/subtask relationships*.

***a. Managing Shared Resources***

Whenever more than one actor or activity requires a limited resource, coordination is required to ensure that the resource is properly allocated among the actors or activities.

***b. Managing Producer/Consumer Relationships***

A producer/consumer relationship is one in which one actor or activity produces something that is used by another actor or activity.

**c. *Managing Simultaneity Constraints***

Simultaneity constraints occur where more than one activity must be performed at the same time as another, or when one activity must be performed at a specific time in relation to the performance of another activity.

**d. *Managing Task/Subtask Relationships***

Task/subtask relationships occur when a task must be broken up into multiple subtasks, and the subtasks divided up among multiple actors or different time periods for completion.

**4. *Davis, Collins, Eierman, and Nance***

Gordon Davis, Rosann Webb Collins, Michael Eierman, and William Nance, in their working paper "Conceptual Model for Research on Knowledge Work" (1991) discuss characteristics of task environment that apply to knowledge tasks rather than manual tasks. They came the closest, of any work with which I am familiar, of attempting to somewhat comprehensively enumerate dimensions of task structure, although I do not believe that their enumeration is complete, or that they even, in some cases, considered the right dimensions. However, some of the characteristics they describe are quite useful. They discuss six characteristics: task activities, time frame, task formalization, task ambiguity, task complexity, and task significance, of which formalization, ambiguity, and complexity are the most suitable for the purposes of this thesis.

**a. *Task Activities***

Davis et al. define task activities as the operations that must be implemented to complete a task, with each activity being associated with one or more problem spaces.

**b. *Time Frame***

The amount of time it will take to complete a task.

**c.      *Task Formalization***

The authors consider task formalization to be the level of specification and structure that is imposed on the performance of the task, or task inputs or outputs. A task with high formalization would be described in a very structured way; there are certain well-defined activities that must be performed in a explicit order to complete the task. In a task with low formalization, though, the activities required to complete the task, and even the goals of the task, would be poorly defined and open to interpretation.

**d.      *Task Ambiguity***

Task ambiguity is defined as the clarity of understanding of the activities that are required to complete a task, or of the inputs or outputs of a task.

**e.      *Task Complexity***

The authors use Wood's (1986) definition of complexity.

**f.      *Task Significance***

Task significance is defined as the value of the task output to the organization performing the task, and the interdependency between task outputs and other operations of the organization.

**5.      *Evaristo, Adams, and Curley***

Roberto Evaristo, Carl Adams, and Shawn Curley, in their article "Information Load Revisited: A Theoretical Model" (1995) describe three task characteristics: time pressure, task formalization, and task complexity. The authors define time pressure as the time available to perform the task, and reiterate Davis et al.'s (1991) definition of task formalization and Wood's (1986) definition of task complexity. Their most interesting contribution is their description of uncertainty, although they do not consider it a task characteristic, but an information characteristic. They define uncertainty as knowledge inadequacy, resulting in an actor's inability to predict something accurately. They further cite the sources of uncertainty as unavailability or incompleteness of information, low information reliability, and information novelty.

## **6. Ben Zur and Breznitz**

Hasida Ben Zur and Shlomo J. Breznitz, in their article "The Effect of Time Pressure on Risky Choice Behavior" (1981) define time pressure as the amount of information that must be considered and processed during one time unit, or as the time allotted for processing a fixed amount of information. Their definition refers to time pressure in the information domain, but it could be generalized to include the task domain as well.

## **C. ENUMERATION OF DIMENSIONS OF TASK STRUCTURE**

The dimensions of task structure are the concepts by which a task can be described. Below is an attempt to comprehensively define the dimensions of task structure that are of interest in experimentation, particularly within the A2C2 context. Nine dimensions are detailed: uncertainty, time pressure, complexity, coordination requirements, magnitude, resources required, information required, task formalization, and dynamicity. These dimensions would ideally be orthogonal, but if complete orthogonality is possible, it would certainly have come at a price in comprehensiveness that I was not willing to pay. Thus, there is some interaction between dimensions (which will be discussed in the section following), although I believe it is minimized. For each dimension of task structure, I give a definition and an example in a military operational context, and then describe how any given task could be graded in that dimension by establishing levels at which the dimension could be measured. I then grade the example given with the definition.

### **1. Uncertainty**

#### ***a. Definition***

Uncertainty is defined as the degree to which information about states, inputs, outcomes, or environments of tasks is unknown (Evaristo, et al., p. 200).

***b. Levels***

This dimension is difficult to quantify, and grading must be done on a subjective basis. There are a number of ways to subjectively grade dimensions, which will be used throughout this chapter. First, anchored scales can be used. Anchored scales are scales of measurement (from 0 to 100, for example) in which illustrations are given of a task that would be graded ("anchored") at various points on the scale, typically the high and the low ends. For example, if "uncertainty" was graded using an anchored scale, an event of which absolutely no information about states, inputs, outcomes, or environments was known would be considered a "0," and an event about which all information about states, inputs, outcomes, or environments was known would be considered a "100." The benefit of an anchored scale is that it allows for a moderate amount of transportability, that is, tasks that are not necessarily being evaluated in terms of one another and are otherwise dissimilar can be compared using a well-anchored scale. Another option for subjectively grading dimensions is to use a scale such as High, Medium, Low, and None. This scale would be adequate in circumstances where the only comparison of tasks that is of interest is between two or more tasks that are generally being evaluated in terms of one another, and are otherwise similar. Grading using this scale is rather arbitrary, depending on the grader's definition of the level, so its transportability is low.

***c. Example***

A simple example of uncertainty would involve an AWACS operator dealing with unknown air tracks. Since the identification and intentions of the aircraft are not known (incomplete information on states, inputs, and environments), the AWACS operator is unsure whether to direct that the aircraft be shot down, warn it away, or let it continue what it is doing (incomplete information on outcomes). This task would be graded as Medium or High uncertainty.

## **2. Time Pressure**

### ***a. Definition***

Time pressure is the amount of activity that must be completed within a given amount of time (Ben Zur and Breznitz, 1981, p. 89). Alternately, it could be defined as the degree to which an individual or group performing a task are stressed by the requirement to complete the task within a given amount of time. I chose time pressure as a dimension rather than Davis et al.'s (1991) task characteristic "time frame," because time frame does not take into account the magnitude of the task at hand, while time pressure, being measured as a rate, does.

### ***b. Levels***

Time pressure could be either represented using a subjective scale, such as High, Medium, Low, or None, or an anchored scale, or a more objective, quantitative scale, depending on the variation of the above definition that is being used. A subjective scale would suggest itself if comparing two or more dissimilar tasks, and the only information the researcher is interested in is whether there is time pressure on the task performer to complete the task within a certain period of time, and what the relative levels between the two or more tasks are. A quantitative scale would suggest itself when comparing tasks which are similar in most dimensions. Time pressure could then be represented as the number of activities or subtasks that must be completed, divided by the time available to complete the task. This method, unfortunately, requires a standard definition of activity or subtask, both in magnitude and duration. If two tasks are equal in the quantitative measure of time pressure described above, but one task's subtasks or activities take significantly longer to perform than the other task's, then the quantitative scale is inappropriate. In situations where the grader cannot with confidence equate the subtasks or activities of one task with those of another, time pressure should be graded using the subjective scale.

*c. Example*

An example of time pressure from the Persian Gulf conflict is a mobile SCUD missile launcher, spotted setting up and preparing to fire. The identification information must be passed from the sensor to a control agency with the assets on hand to destroy the launcher, an asset must be assigned to destroy the launcher, the asset must travel to the launcher, and the asset must destroy the launcher, all in a matter of a few minutes\*. This task has High time pressure, on a subjective scale. On an objective scale, if identifying, passing information, assigning an asset, getting in position to attack, and attacking are all considered subtasks, and the time available is 10 minutes, then time pressure is 5/10 or 0.5 subtasks per minute.

**3. Complexity**

I chose a variation on Campbell's (1988) definition of complexity over Wood's (1986), for several reasons. First, Campbell's four characteristics of complexity are more easily understood than Wood's three components of complexity, and are more simply measurable. Second, Wood's description of coordinative complexity is very close to Malone and Crowston's (1994) definition of coordination, which I chose to include as a separate dimension listed in paragraph four below. Finally, Wood's concept of dynamic complexity is generalizable to all dimensions of task structure, not just complexity, and it is included as dynamicity, in paragraph nine below.

Complexity, then, can be defined as the degree to which a task contains five task characteristics: multiple attributes, multiple paths, multiple outcomes, conflicting interdependence among outcomes, and uncertain or probabilistic linkages (Campbell, 1988, p. 43). Multiple attributes has been added to Campbell's original list of four characteristics on the basis of other articles. Specific definitions of the five task characteristics are as follows:

---

\*This was rarely, if ever, successfully done during the Persian Gulf conflict.

**a. Multiple Attributes**

(1) Definition. The number of attributes that a task performer must take into account, or more than one thing that must be taken into consideration in order to complete the task, directly affect task complexity. The more attributes a task has, the more complex it is.

(2) Levels. Multiple attributes is graded by the number of attributes that must be taken into consideration.

**b. Multiple Paths**

(1) Definition. The number of paths that could be taken to arrive at a desired outcome (Campbell, 1988, p. 43).

(2) Levels. This aspect of complexity is graded by the approximate number of paths that could be taken to arrive at the desired endstate. In many cases, this number could be infinite, or approach infinity. When this is true, the evaluator should only count the major variations of paths.

**c. Multiple Outcomes**

(1) Definition. The number of outcomes desired from a task. These outcomes need not be mutually exclusive (Campbell, 1988, p. 43).

(2) Levels. This aspect is graded by the number of different outcomes that the task performer needs to achieve.

**d. Conflicting Interdependence Among Outcomes**

(1) Definition. Conflicting interdependence among outcomes is a negative relationship between desired outcomes. If achieving one desired outcome conflicts with achieving another desired outcome, complexity increases (Campbell, 1988, p. 44).

(2) Levels. Conflicting interdependence among outcomes can be graded by counting the number of conflicts between instances of subparagraph (c) above. Each conflict should then be given a grade of 1 if the conflict is minor, 2 if it is moderate, and 3 if it is severe, or some similar scale. These grades should then be totaled across all conflicts so that each task has a single, numerical grade.

**e.      *Uncertain or Probabilistic Linkages***

(1) Definition. The condition where the connection between the potential path activities and the desired outcomes from a task are uncertain, or probabilistic (Campbell, 1988, p. 45).

(2) Levels. High, Medium, Low, or None.

**f.      *Example***

A good general example of complexity is the conduct of an amphibious assault. The amphibious assault task contains *multiple attributes* (terrain, hydrography, enemy positions, roads, beaches, enemy reinforcement capability, etc.) One desired outcome of the task is to destroy or suppress enemy positions at or near the beachhead. There are several ways to do this (*multiple paths*), such as to use close air support, naval gunfire, infiltrate SEAL or reconnaissance teams, or some combination. There are also many additional outcomes (*multiple outcomes*) that are desired, such as to achieve surprise and minimize casualties. However, achieving surprise and destroying and suppressing enemy positions are usually mutually exclusive (*conflicting interdependence among paths*) — if the commander precedes his amphibious assault with a heavy air and sea bombardment, he will stand a good chance of destroying or suppressing the enemy positions, but he will probably destroy the element of surprise. Finally, if the enemy's positions at or near the beach are well protected and disguised, the commander is uncertain whether his possible actions of close air support, naval surface fire support, etc. will be able to successfully achieve his desired outcome of suppressing or destroying the enemy positions (*uncertain or probabilistic linkages*).

This example would be graded as follows:

(1) Multiple Attributes: The task attributes that must be considered in an amphibious assault are objective, time available, terrain, weather, hydrography, friendly forces available, enemy positions, enemy reinforcements, enemy air threat, enemy sea threat, enemy anti-air threat, beaches, mobility on land, and non-combatants, for a total of 14. These are very high-level attributes, so it would be inappropriate to compare this task with a task in which the attributes were low-level.

(2) Multiple Paths: The number of paths that could be taken to conduct an amphibious assault is infinite. They can be categorized into major variations, however. The major paths that could be taken are to conduct the assault (as an across-the-beach assault, vertical envelopment, or combination) with extensive air and naval surface fire support beach preparation, conduct the assault without extensive air and naval surface fire support beach preparation, conduct the assault while destroying/suppressing enemy positions using stealthy means (SEAL/Recon teams/Information Warfare), or any of the three previously mentioned paths, plus a feint at a different location, for a total of 6 possible major paths.

(3) Multiple Outcomes: High-level desired outcomes for the given amphibious assault task are to (a) accomplish the objective, (b) achieve surprise, (c) suppress enemy positions at the beach, (d) minimize casualties, (e) interdict enemy reserves, (f) achieve sea supremacy, (g) achieve air superiority, and (h) minimize collateral damage, for a total of 8 desired outcomes.

(4) Conflicting Interdependence Among Outcomes: Conflicts, and the scores for each, are shown in Table 1 (correlate letters on table with outcomes listed in paragraph above). It should be noted that the scoring in Table 1 is situationally dependent; conflicts between outcomes would vary in different amphibious operations.

	a	b	c	d	e	f	g	h
a	—	0	0	2	0	0	0	1
b	xx	—	3	1	2	2	2	0
c	xx	xx	—	1	2	1	1	2
d	xx	xx	xx	—	0	0	0	3
e	xx	xx	xx	xx	—	1	1	2
f	xx	xx	xx	xx	xx	—	1	2
g	xx	xx	xx	xx	xx	xx	—	1
h	xx	xx	xx	xx	xx	xx	xx	—
Totals	0	0	3	4	4	4	5	11
								31

Table 1. Scoring of Conflicting Interdependence Among Outcomes, Where Each Entry On Table Represents The Conflict Between The Outcomes Represented in Column i and Row j

(5) Uncertain or Probabilistic Linkages: Depending on the situation and the accuracy and volume of intelligence available, this could vary from low to high.

#### 4. Coordination Requirements

##### a. Definition

Generally, coordination requirements is the degree to which dependencies between activities must be managed (Malone and Crowston, 1994, p. 90). This can be subdivided into external (the group with others) and internal (among members of the group) coordination. Four different types of dependencies that must be coordinated, and an example of each, are as follows:

(1) Shared Resources. Who, among a group of actors, gets which available and common resources (Malone and Crowston, 1994, p. 92).

(2) Producer/Consumer Relationships. When one member of a group uses the output of another, or a member of a group or the group as a whole uses the

output of another entity, or this other entity uses the group's or a member of the group's output (Malone and Crowston, 1994, p. 93).

(3) Simultaneity Constraints. When two or more activities must be scheduled or synchronized (Malone and Crowston, 1994, p. 95).

(4) Task/Subtask. Goal selection and/or task decomposition within a group and/or among groups (Malone and Crowston, 1994, p. 95).

***b. Levels***

A task would be given a grade for each of the four different types of dependencies listed above, and on both the internal and external level. Subjective grades such as High, Medium, Low, and None are probably most appropriate. Thus, each task would have eight coordination requirements grades associated with it.

***c. Example***

(1) Shared resources: Two light infantry units each face an enemy armored threat, and there is only one section of antitank helicopters that can be used against those threats, and it is attached to one of the infantry units. Coordination required would be graded as High (internal) and Low (external). If the antitank helicopter asset is owned by an external agent, however, coordination required would be graded as Low (internal) and High (external).

(2) Producer-consumer relationships: During the conduct of an amphibious assault, mineclearing helicopters must be used to clear mines from the approach to the landing beach. The landing force, then, is the consumer of the mineclearing helicopters' output. If we consider the "group" to be the amphibious task force, then coordination required would be High (internal) and Low (external). If we consider the "group" to be the landing force, however, then coordination required would be Low (internal) and High (external).

(3) Simultaneity constraints: During the latter stages of the same amphibious assault, an infantry unit must conduct an attack synchronized with close air support and naval surface fire support. If the "group" was considered to be the amphibious task force, the coordination required would be High (internal) and Low (external). If the "group" was considered to be the landing force, the coordination required would be Low (internal) and High (external).

(4) Task/Subtask: A landing force commander is given a mission of taking a specific objective. He must then divide the task up into subtasks for his subordinate units to complete. The coordination required in this situation would be High (internal) and Low (external).

## **5. Magnitude**

### ***a. Definition***

The magnitude of a task is the number of activities or subtasks that must be performed in order to complete the task.

### ***b. Levels***

The magnitude of a task could be determined quantitatively by the number of activities that must be performed in order to complete the task. However, this requires a standardized definition of "activity," such that one activity is as difficult to perform as another, and decomposition of the task to the point where all activities are identified. Another way to assess the magnitude of a task would be to use an anchored scale. For example, magnitude could be measured on a one to one hundred scale, with "one" representing the task of pressing the spacebar on a typewriter, and "one hundred" representing the task of constructing the United States Interstate Highway System.

### ***c. Example***

The task of conducting an amphibious assault has many different activities or subtasks that must be performed, such as clearing the beach, making a reconnaissance,

suppressing artillery with close air support, et cetera. On the one to one hundred scale mentioned above, the score would be about 30 for a significant amphibious assault.

## **6. Resources Required**

### ***a. Definition***

Resources required to complete a task is defined as the resources other than information that the actors must possess in order to successfully complete the task in question.

### ***b. Levels***

Resources required could be measured quantitatively by the number of resources required to complete a task, or could be graded on a subjective "High, Medium, and Low" scale. As is the case with magnitude, one must take care to ensure that there is a standard definition of resource, so that five resources in one instance is the same as five resources in another.

### ***c. Example***

A landing force is given the mission of attacking an objective, and that objective requires three infantry companies to effectively overwhelm it. If the "base unit" of resources is one infantry company equivalent, then resources required to complete this task is three.

## **7. Information Required**

### ***a. Definition***

Information required to complete a task is the information that the actors must possess in order to successfully complete the task in question.

### ***b. Levels***

Information required is measured using the same method as resources required.

*c. Example*

A Silkworm anti-ship missile site threatens an aircraft carrier battle group. However, it was reported in a residential area, so additional information (confirmation and precise location via U-2 imagery) is required before the commander can destroy that threat. If the base unit of information is one intelligence report, then information required to complete this task is two reports, the initial report and the confirmation report.

**8. Task Formalization**

*a. Definition*

Task formalization is the level of specification and structure exhibited by the task (Davis et al., 1991, p. 22). A task with high formalization is defined in a very structured way; there are certain well-defined activities that must be performed in a definite sequence in order to complete the task. In a task with low formalization, though, the activities required to complete the task, and possibly even the goals of the task, are poorly defined and open to interpretation.

*b. Levels*

This dimension is again quite subjective, and the levels should probably be High, Medium, Low, and None, or some other discrete scale.

*c. Example*

The task of calling for artillery fire against a visible target is very well structured. There are precise procedures that the forward observer must follow, using specific radio nets and message formats, that are ingrained from his earliest training. Task formalization for an artillery call for fire is High. However, the task of infiltrating enemy lines and destroying a prepared defensive position is not well structured — there are many ways that the task could be carried out, and the methods used and paths taken are not well formalized, but situationally dependent. Task formalization for the infiltration task is Low.

## **9.     Dynamicity**

### ***a.     Definition***

The dynamicity of a task is the degree to which one or more of the dimensions of the task changes over time. Dynamicity could refer to any of the dimensions described above, alone or in combination with others.

### ***b.     Levels***

This is quite subjective, and would probably best be graded as High, Medium, Low or None in each dimension, or possibly the number of changes per unit time in each dimension, if that is measurable.

### ***c.     Example***

Returning to our amphibious assault example, consider the task of conducting the assault across the beach. If the assault was conducted while the amphibious task force was still over the horizon, and retained the element of surprise, the task would be much different than if it was conducted later, when the amphibious task force was in view of the objective beach, and the element of surprise was lost. The later it was conducted, the better prepared the enemy would be for the assault. In each dimension, dynamicity is graded as follows:

Uncertainty: High (The later the assault is conducted, the less uncertainty)

Time Pressure: High (The later the assault is conducted, the more time pressure)

Complexity: High (The later the assault is conducted, the more complexity)

Coordination Requirements: High (The later the assault is conducted, the more coordination required)

Magnitude: High (The later the assault is conducted, the greater the magnitude)

Resources Required: High (The later the assault is conducted, the more resources required)

Information Required: High (The later the assault is conducted, the more information required)

Task Formalization: Low

#### **D. EXCEPTIONS TO ORTHOGONALITY**

The dimensions described in the preceding section are distinct, but, unfortunately, related. However, if the interrelations between dimensions are known, compensation for the interaction can be made in order to keep dimensions the experimenter wants to remain constant from varying. This section will discuss how one might expect changes in one dimension to affect all other dimensions.

There should be little or no interaction between uncertainty and dynamicity, time pressure and dynamicity, complexity and dynamicity, coordination requirements and task formalization, coordination requirements and dynamicity, magnitude and task formalization, magnitude and dynamicity, resources required and task formalization, resources required and dynamicity, information required and task formalization, information required and dynamicity, or task formalization and dynamicity. All other interactions are detailed below.

##### **1. Uncertainty-Time Pressure**

As uncertainty increases, the number of activities that an actor would have to perform in order to deal with the uncertainty well enough to complete the task could also increase (increased magnitude). If this number of activities increases while the time allowed to perform the task remains constant, time pressure will increase. Conversely, if time pressure increases, it could force the actor to complete the task before he is able to obtain all the information he wants, thus increasing uncertainty.

##### **2. Uncertainty-Complexity**

As uncertainty increases, complexity can also increase. The number of attributes that must be taken into account in order to reduce uncertainty can increase, thus causing greater complexity. Additionally, if the uncertainty decreases the probability of the linkages between path activities and desired outcomes, this can cause an increase in complexity. Conversely, if the complexity increases, it should not necessarily affect the uncertainty.

### **3. Uncertainty-Coordination Requirements**

Changes in uncertainty can cause changes in coordination requirements. If uncertainty increases, whether resources must be shared, which activities must be simultaneous, what must be produced and consumed, or which subtasks are required in the performance of a task can also become more uncertain, requiring greater coordination for any type of dependency in which the uncertainty is increased. Conversely, changes in coordination requirements should not cause changes in uncertainty.

### **4. Uncertainty-Magnitude**

As mentioned under "time pressure," as uncertainty increases, the number of activities that an actor must perform in order to alleviate the uncertainty could increase, thus increasing the magnitude of the task. Conversely, an increase in magnitude could force the actor to complete the task before he is able to obtain all the information he wants, thus increasing uncertainty.

### **5. Uncertainty-Resources Required**

As uncertainty increases, resources required could increase, if those resources would be used to decrease the uncertainty or, in a case that involves two or more uses for certain resources, the uncertainty is enough so that the decisionmaker desires to use resources for all potential paths, in order to "cover all bets." An increase in resources required would not tend to drive an increase in uncertainty, however.

### **6. Uncertainty-Information Required**

As uncertainty increases, information required could also increase, because the decisionmaker would want more information in order to reduce his uncertainty. Changes in information required, though, should not cause changes in uncertainty.

### **7. Uncertainty-Task Formalization**

Increases in uncertainty could also elicit increases in task formalization, since the uncertainty can involve the structure and paths taken to complete the task. This is not necessarily so, however; a task can still be highly formalized and well structured if some

or many of the states, inputs, outcomes, or environments are not well known. Changes in task formalization should not drive changes in uncertainty, however.

#### **8. Time Pressure-Complexity**

Changes in time pressure can cause changes in complexity. If the time pressure decreases, the number of attributes or paths that can be considered can increase, because of the additional time the decisionmaker has to consider them. Also, uncertain or probabilistic linkages can decrease if time pressure decreases, because the decisionmaker has additional time to reduce his uncertainty. Conversely, changes in complexity can cause changes in time pressure. If complexity decreases, the amount of time that the decisionmaker must devote to sorting out the situation also decreases, and, if the amount of time available remains constant, time pressure will decrease.

#### **9. Time Pressure-Coordination Requirements**

Changes in time pressure can affect coordination requirements. If the time pressure increases, coordination between two or more entities can become more difficult, or even impossible, because the time available to communicate and synthesize is lessened. Conversely, changes in coordination requirements can cause changes in time pressure. If coordination requirements are lessened, the amount of activities that must be performed is generally lessened, because some of those activities are coordination-related, such as the actors communicating with one another. Lessening the number of activities while holding the time available constant reduces time pressure.

#### **10. Time Pressure-Magnitude**

Since time pressure and magnitude are directly related (time pressure is magnitude divided by time available), changes in one will cause changes in the other, unless the time available is modified accordingly.

#### **11. Time Pressure-Resources Required**

Changing time pressure would tend to have an inverse effect on resources required. If time pressure was increased, the resources required would tend to go down,

because the actors would not have time to use all the resources that are available to them. Changes in resources required would tend to have a direct effect on time pressure — if resources required was increased, then time pressure would increase, because of the additional activities that would probably be required to put those resources to use, as long as time available is held constant.

## **12. Time Pressure-Information Required**

This interaction should be the same as the time pressure-resources required interaction.

## **13. Time Pressure-Task Formalization**

As time pressure is increased, task formalization would tend to increase, in those instances where there is a more structured way to perform a task that may not achieve the goals of the decisionmaker as well as a less structured method will, but the more structured method would tend to take more time. As task formalization is increased, time pressure would tend to decrease, because more formalized tasks would tend to take less time because of the well-defined nature of the activities involved.

## **14. Complexity-Coordination Requirements**

Complexity and coordination requirements can affect each other in many subtle ways. For instance, if the number of possible paths is increased, coordination requirements could be increased, because of a possible requirement to coordinate with other team members in order to explore the paths. Or, increasing a shared resources requirement could increase the number of possible paths that could be taken. Changes to either of these dimensions must be scrutinized carefully to ensure any effect on the other has been accounted for.

## **15. Complexity-Magnitude**

Increasing complexity can increase the magnitude of a task. If, for instance, additional activities must be performed in order to resolve a complex issue, then magnitude will increase. Additionally, if the magnitude of a task changes, and the added

or decreased activities affect the number of attributes, paths, outcomes, interdependence, cues, or linkages present, then the complexity could increase or decrease as well.

#### **16. Complexity-Resources Required**

Increasing complexity of a task might require a different system or more personnel to aid in problem-solving than a more simple task would, thus increasing resources required. If resources required to complete a task were decreased, then complexity could decrease also, because the decrease in resources required could result in fewer attributes or paths that must be considered by the decisionmaker.

#### **17. Complexity-Information Required**

Increasing the complexity of a task could increase information required, because the decisionmaker might want more information in order to help choose the right path, or decrease uncertainty of linkages between paths and outcomes. Increasing the information required could also increase task complexity, because the additional information required could be an additional attribute that the decisionmaker must consider.

#### **18. Complexity-Task Formalization**

Increasing complexity can decrease task formalization. As the number of attributes, paths, and desired outcomes grows, the chore of formalizing a task can become more difficult, such that many extremely complex tasks are not formalized at all, because of the number of characteristics that must be considered. Increasing task formalization may or may not increase complexity. Increasing formalization and adding a structured way of looking to the decisionmaking process could have the effect of decreasing complexity, or at least making the complexity more easily manageable.

#### **19. Coordination Requirements-Magnitude**

Increasing coordination requirements could increase the magnitude of a task, because greater coordination requirements could result in additional activities that must be performed in order to coordinate actions. Changes in task magnitude, however, should have little or no effect on coordination requirements, unless the activities that were added

or deleted specifically involve use of shared resources, a producer/consumer relationship, a simultaneity constraint, or the task must be decomposed into subtasks by the decisionmakers.

#### **20. Coordination Requirements-Resources Required**

Changes to the coordination requirements should not affect resources required to perform a task. Increases in resources required, though, could cause coordination requirements to increase, because the additional resources required could cause a necessity to share available resources where one did not exist before, unless the resources available were also increased.

#### **21. Coordination Requirements-Information Required**

Changes to coordination requirements should not affect information required. Increases in information required could lead to increases in coordination requirements, because the decisionmakers might need to coordinate actions in order to obtain the additional information.

#### **22. Magnitude-Resources Required**

Changes in the magnitude of a task should not affect resources required to complete a task, unless the added activities require more resources to perform them. Changes in resources required, however, could change the magnitude of a task, if the additional resources needed additional activities to be performed in order to put the new resources to use.

#### **23. Magnitude-Information Required**

Changes in the magnitude of a task should not affect information required to complete a task, unless the added activities require more information in order to perform them. Changes in the information required, however, could change the magnitude of a task, if the actors had to perform additional activities in order to obtain the added information.

## **24. Resources Required-Information Required**

Changes in resources required to complete a task could cause changes in information required, if the additional resources needed additional information in order to put the resources to use. Conversely, changes in information required to complete a task could result in changes in resources required, if the new information requirement needed additional resources in order to obtain the information.

### **E. SUMMARY**

The purpose of this chapter was to enumerate dimensions of task structure, define them, and develop a method of grading the dimensions, so these dimensions can be held constant or varied in an experimental environment. The chapter began with a review of the pertinent literature, surveying the possible sources of information and different opinions on dimensions of task structure. These dimensions were then compiled, revised, and extended into what the author believes is a comprehensive breakdown of the dimensions of task structure. A summary of these dimensions, and the levels at which they can be graded, is included in Table 2 below.

Examples of each dimension were then given, and graded using the scale that was developed. Finally, the author described exceptions to the requirement that the dimensions be orthogonal to one another, to aid in adjusting for any effect changing one dimension might have on other dimensions.

<b>Dimension</b>	<b>Levels</b>
Uncertainty	High, Medium, Low, None
Time Pressure	High, Medium, Low, None (or Magnitude/Time Available)
Complexity <ul style="list-style-type: none"> <li>- Multiple Attributes</li> <li>- Multiple Paths</li> <li>- Multiple Outcomes</li> <li>- Conflicting Interdependence Among Outcomes</li> <li>- Uncertain or Probabilistic Linkages</li> </ul>	Number of attributes Number of paths Number of outcomes Number of conflicts, levels of each, totaled for task High, Medium, Low, None
Coordination Requirements <ul style="list-style-type: none"> <li>- Shared Resources</li> <li>- Producer/Consumer Relationships</li> <li>- Simultaneity Constraints</li> <li>- Task/Subtask</li> </ul>	For all types of dependencies: High, Medium, Low, None, for internal and external coordination
Magnitude	Number of activities or subtasks
Resources Required	Number of resources required
Information Required	Number of pieces of information required
Task Formalization	High, Medium, Low
Dynamicity	High, Medium, Low for each dimension

Table 2. Dimensions of Task Structure

### **III. TASK STRUCTURE DIAGRAM AND TASK DESIGN PROCESS**

#### **A. INTRODUCTION**

As discussed in the previous chapter, determination of the dimensions of task structure is an important aspect of experimental design involving task structure, since it provides the groundwork for varying or controlling tasks based on dimensions. Once those dimensions are defined, it would be of further assistance to the experimenter to develop a method for visually describing the task structure, flow, and as many of the dimensions defined in the previous chapter as possible. A visual method of this sort would make the undertaking of causing tasks to differ or remain constant in various respects simpler.

The focus of this chapter is the development of a task structure diagram concept. First, I will give some preliminary definitions necessary to the discussion of decomposition of tasks into component subtasks and actions. I will then describe the task structure diagram that I developed, and define the specific features and capabilities of the diagram. Then, I will describe how the dimensions of task structure developed in the previous chapter relate to the diagram. Finally, I will synthesize the concepts of Chapter II and this chapter into a task design process that can be used to develop a military operational scenario, or more general task, in an experimental context.

#### **B. DEFINITIONS**

Because the development of a task structure diagram will involve decomposing tasks into the smaller activities of which they are constituted, it is necessary to define exactly what those different activities should be called, and to define task structure and the task structure diagram. These definitions apply throughout this thesis.

##### **1. Activity**

An activity is any act that must be performed, at a high or low level of task decomposition. For our purposes, it is a generic term encompassing tasks, subtasks, and actions.

## **2. Task**

A task is the macro level activity. It describes the overall activity that is being performed by the actors. Since it is really impossible to define beforehand the magnitude of the task, for our purposes, it is defined as the level that is the primary focus of the study.

## **3. Subtask**

A subtask is a next-lower level component of a task. The nodes on a task structure diagram are subtasks. There can be more than one level of subtasks; if there are multiple layers, the highest layer of subtasks is subtask level 1.

## **4. Action**

Actions are activities that are in their most elemental state for the uses of the study. Actions are either not further decomposable, or further decomposition would be impractical or would serve no purpose.

## **5. Task Structure**

Task structure is defined as the flow of subtasks within a task in the time domain.

## **6. Task Structure Diagram**

A task structure diagram is a visual model of a task which describes the task structure, and as many characteristics of a task as practical. The task structure diagram is designed to simplify understanding of the task and manipulation of potential variables.

## **C. TASK STRUCTURE DIAGRAM**

The task structure diagram I developed is based loosely on the data flow diagram (DFD) concept (Hatley and Pirbhai, 1988, p. 13). The purpose of this task structure diagram is to provide a visual representation of the flow of subtasks and actions, possible paths, simultaneity constraints, competition, prerequisites, resources and information required, decomposability, and dynamicity of subtasks within a task to experimental designers. Many of the dimensions of task structure in the previous chapter are

represented directly in this task structure diagram; others can be inferred from it. By visualizing the structure of a task in this way, experimenters are more able to determine if that task accomplishes the objectives that have been set. In addition, the task structure diagram provides a straightforward, visual method for comparing it with other tasks and for describing a task to those outside the scenario design process. This method also enables design from the other direction — experimental designers can delineate a task structure that they are interested in testing, and the scenario can be written to conform to that structure. It further promotes the “object oriented” view of task structure design, allowing designers to rearrange activities and nodes visually, as modules, to achieve experimental goals.

Clearly, tasks with high levels of task formalization, or highly structured tasks, are most easily described by this type of method. As one moves down the scale from high formalization to low, the possible paths that could be taken grow exponentially, until a point is reached where the labor involved in developing this sort of diagram outweighs the benefits to be gained from its use. Figure 2 is an example of the task structure diagram developed in this chapter. The primitives, or building blocks, of the proposed method are described below.

### **1. Flow Description**

In this method, the task is considered to encompass the entire diagram; the individual subtasks are the nodes, represented by the circles or rectangles. The task flows in time from the “start” box to the completion of the final subtask.

### **2. Actors**

The actor who is performing each subtask in Figure 2 is represented by the style of type used for the name of the subtask. If the subtask is given in bold type, then Unit 1 is the task performer, while if the name of the subtask is given in italic type, then Unit 2 is the task performer. If the subtask is in normal type, then both actors are involved in the subtask. If there are more than two actors involved in a task, then different combinations and fonts would have to be used.

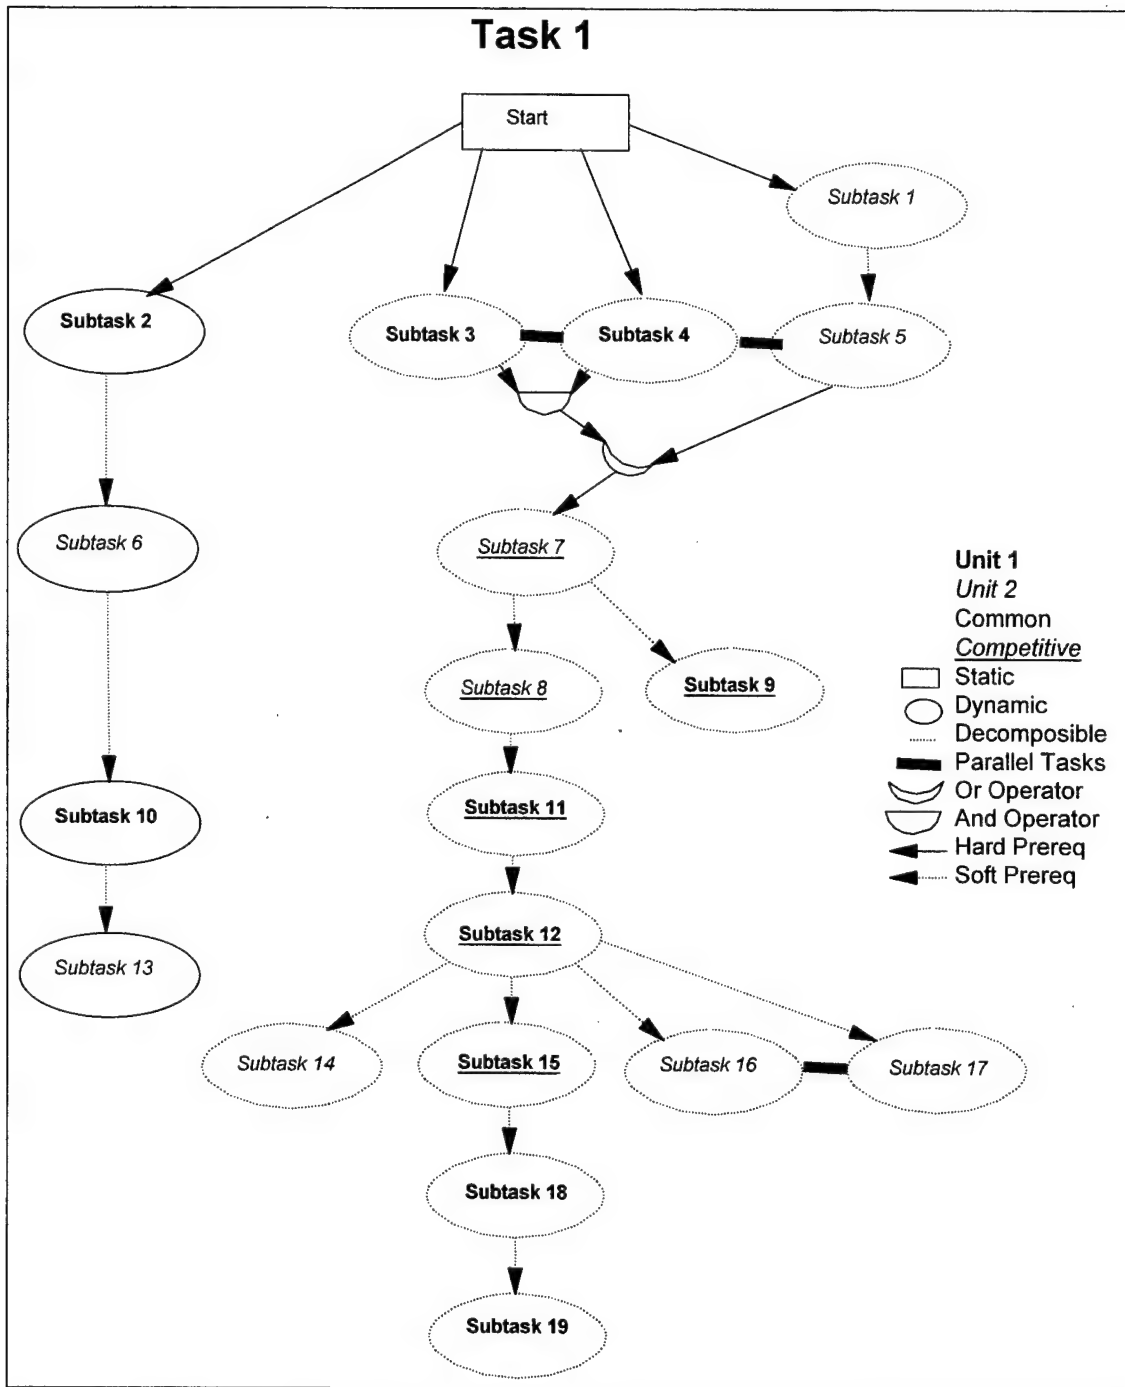

Figure 2. Task/Subtask Level Task Structure Diagram

### 3. Decomposability

Decomposability is defined as the ability to further divide the task, subtask, or activity into lower level subtasks or actions (Simon, 1981, pp. 196-210). Decomposability is represented by the border of the rectangle or oval representing each

activity. If the border is solid, that means the subtask is not decomposable — the task, subtask, or action represented is at its most basic level. If the border is a dotted line, then the activity can be further decomposed.

#### **4. Simultaneity**

Simultaneity, from Chapter II, is defined as the requirement for two or more activities to be performed at the same time or synchronized, and is a type of dependency between actions that is encompassed within the aegis of coordination requirements. Simultaneity is represented by a thick bar connecting the two activities that have the dependency relationship.

#### **5. And Operator**

The And operator is represented in the diagram by a half-moon shape. It represents the requirement for both of the previous activities to be completed before the next can be performed.

#### **6. Or Operator**

The Or operator is represented in the diagram by a crescent shape. It represents the requirement for either one of the previous activities to be completed before the next can be performed.

#### **7. Competition**

Whether an activity is competitive or non-competitive describes another of the coordination requirements dependencies, shared resources. A competitive task is one in which two or more actors need the same resource to complete the task. Competition over resources is represented in the diagram by underlining the title of the activity; if the title of the activity is not underlined, then there is no competition over resources for that activity.

## **8.      Dynamicity**

Dynamicity, from Chapter II, is the degree to which one or more of the dimensions of a task changes over time. Dynamicity is represented in the diagram by the shape of the figure representing the activity. Rectangles represent non-dynamic, or static tasks, and ovals represent dynamic tasks.

## **9.      Prerequisites — Hard And Soft**

Prerequisites are the activities that are to be performed prior to a given activity. If it is not possible to perform the given activity without the prerequisite being performed first, then that prerequisite is considered a hard prerequisite. If it is possible, but not optimal, to perform the given activity without the prerequisite being performed first, then that prerequisite is considered a soft prerequisite. A hard prerequisite is represented in the diagram by a solid arrow connecting two activities, while a soft prerequisite is denoted by a dashed arrow connecting two activities.

## **10.     Decomposing Tasks Into Subtasks And Actions**

Figure 2 shows a task decomposed into subtasks. Some of the subtasks shown are in their elemental state — they are not further decomposable. Most, though, can be decomposed at least one level. Figure 3 shows a subtask decomposed into its component actions.

The task structure diagram in the elemental state follows the same format as the previously discussed task structure diagram. The only significant differences are that the task structure diagram in the elemental state also contains the breakdown of the dimensions of task structure that apply to each action that are not otherwise manifested in the task structure diagram (if they are graded as other than “Low” or “None”), and the resources and information required to complete the action.

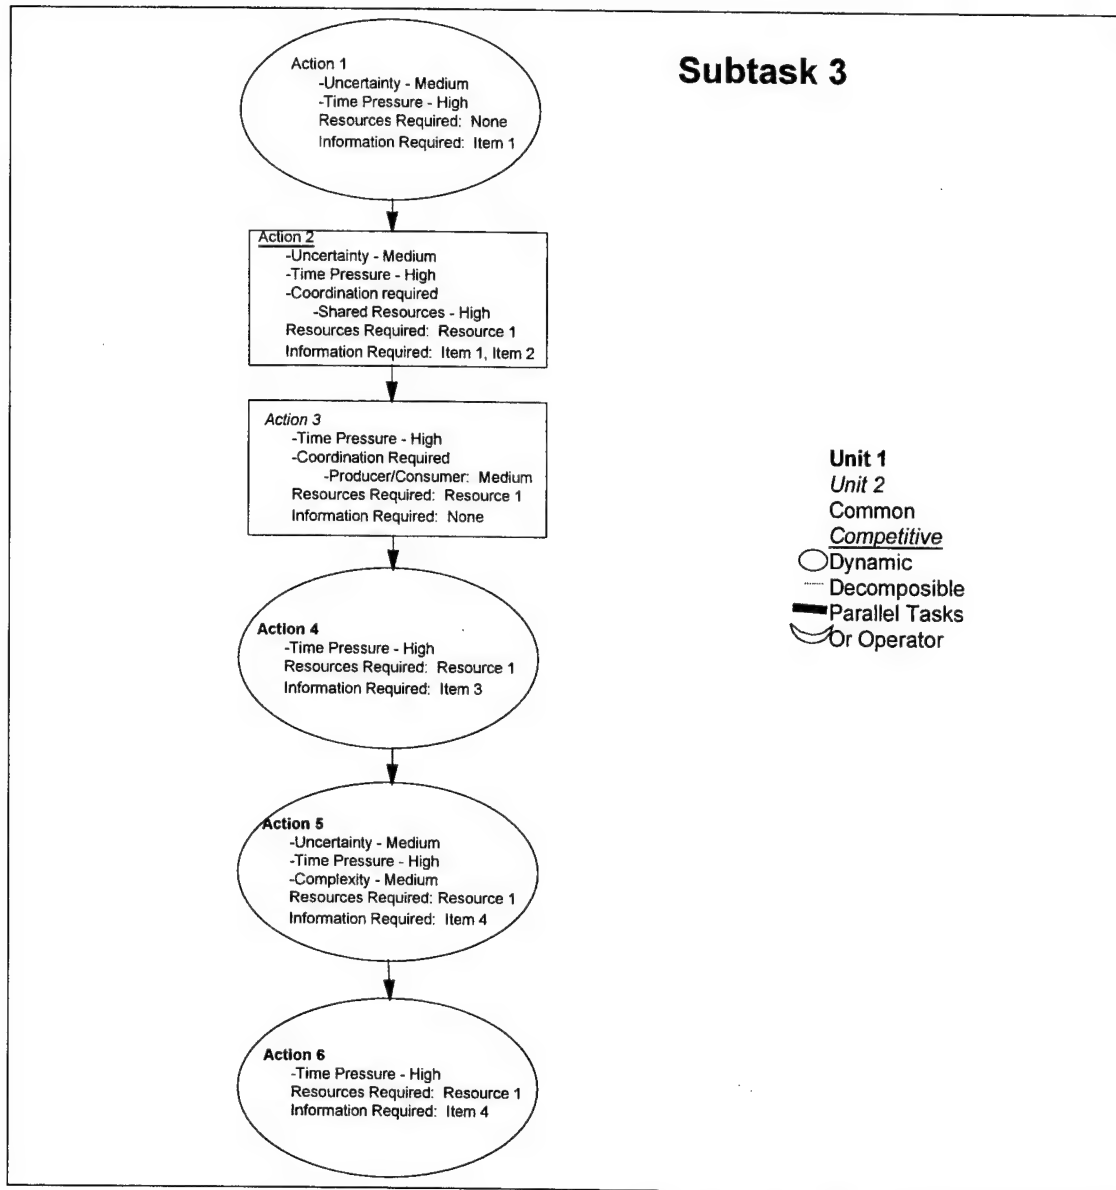

Figure 3. Subtask Decomposed To Its Most Basic Components

#### D. OPERATIONALIZING DIMENSIONS OF TASK STRUCTURE IN A TASK STRUCTURE DIAGRAM

An important consideration for both the task structure diagram just discussed and the dimensions of task structure enumerated in the previous chapter is the linking of the two issues. How is each dimension of task structure implemented in the task structure diagram? Implementation of some dimensions is straightforward, while others must be

handled more subtly. This section describes how each of the nine dimensions of task structure is manifested in the task structure diagram.

### **1. Uncertainty, Time Pressure, Complexity**

Uncertainty, time pressure, and complexity are manifested in the task structure diagram by the level that each is given in the diagram that decomposes a task into its most elemental state, as shown in Figure 3. The overall score for a subtask in each of these dimensions is the mean of all scores of the actions that comprise the subtask; the overall score for a task in each dimension is the mean of all scores of the subtasks that comprise the task.

### **2. Coordination Requirements**

Coordination requirements are manifested in several ways in the task structure diagram. First, if the grade for each type of dependency is High or Medium, this will be listed with the action at which it is present on the diagram that decomposes the task to its most elemental state. In addition, the individual dependencies are represented separately in the diagram as follows:

#### ***a. Shared Resources***

In Figure 2, subtasks that are underlined are competitive events. This is synonymous with competition over shared resources. When activities are underlined, competition over shared resources is Medium or High.

#### ***b. Producer/Consumer Relationships***

The presence of a hard prerequisite indicator (solid arrow connecting two activities) in a task structure diagram implies that a producer/consumer dependency exists, since the follow-on activity cannot be performed until the first is complete. When the solid arrow is present, the producer/consumer dependency is graded as Medium or High.

*c.      **Simultaneity Constraints***

Simultaneity is represented in the task structure diagram by a solid bar connecting the activities that have the dependency relationship. When the solid bar is present, simultaneity constraints is graded as Medium or High.

*d.      **Task/Subtask***

While the task structure diagram captures the breakdown of a task into its component subtasks and actions, this is not the same as the conscious decomposition of the task by the actors into portions for each to accomplish which the task/subtask dependency represents. The task/subtask dependency is not manifested in the diagram itself, other than the grade given in the diagram that decomposes the task to its most elemental state.

**3.      Magnitude**

The magnitude of a task can be measured from the task structure diagram by breaking the entire task down into its most elemental state and generating one or more diagrams similar to Figure 3. Counting the total number of actions in these diagrams gives the task's magnitude.

**4.      Resources And Information Required**

Resources and information required are given in the diagram that decomposes the task to its most elemental state. Counting the total resources and pieces of information in the diagram(s) representing the totality of actions within the task gives the total resources and information required for the task.

**5.      Task Formalization**

A task that is amenable to description using the task structure diagram will probably have at least a Medium level of task formalization. Indicators of formalization in the diagram are the relative number of soft and hard prerequisites (more soft prerequisites would imply less formalization), and the number of "or" operators (more "or" operators implies less formalization).

## **6.     Dynamicity**

Dynamicity, as discussed earlier, is manifested in the task structure diagram by the shape of the node representing the activity.

## **E.     TASK DESIGN PROCESS**

The activities described in this and the previous chapters can be applied to the task design and scenario development problem stated in Chapter I in a straightforward manner. The steps in the process are: determining the dimension of task structure of interest, determining the desired task structure, developing the scenario, and grading scenarios by dimensions. The second and third steps can be interchanged. This process will often be iterative, with at least the second, third, and fourth steps repeated one or more times.

### **1.     Dimension of Interest**

Determining the dimension(s) of task structure of interest depends on the goals of the experiment. Of course, in order for there to be a task structure dimension of interest, task structure must be an independent variable. For example, if a researcher wanted to determine whether larger or smaller tasks were performed better by a certain organizational structure in a specific environment, then his dimension of interest would be *magnitude*. He should also determine the number of levels he will need ahead of time, based on the constraints of his experiment, and at least an approximate figure for the values the levels will take on.

The researcher should also determine the levels of any of the other dimensions of task structure that he desires to hold constant, if that is important to his investigation.

### **2.     Desired Task Structure**

If a certain structure within the task-subtask-action decomposition, or one of the characteristics that is best reflected in a diagram (such as parallelism), is desired, then a preliminary task structure diagram should be developed after the dimension of interest has been determined, with detail filled in as the scenario is written. If there is no specific

task structure requirement for the experiment, then the task structure diagram should be developed concurrently with the scenario, to be used as a briefing, explanation, editing, and grading tool.

### **3. Scenario Development**

The scenario should be developed based on the above two steps, and to fit within the other constraints of the experiment, such as project context, other independent variables, subject pool, time and resources available, et cetera.

### **4. Grading Dimensions of Task Structure in Scenarios**

Finally, the scenario(s) should be graded based on the levels of dimensions of task structure described in Chapter II, in order to ascertain whether these dimensions differ or are held constant as was intended.

## **F. SUMMARY**

This chapter further developed the concepts of the previous chapter by stipulating a method by which a task's structure can be visually represented. This diagram not only depicts the dimensions of task structure, but also shows the flow of subtasks and actions in the time domain, and represents optional paths, prerequisites, and decomposability. The chapter began with several definitions necessary in order to discuss task decomposition. Then, the task structure diagram and its features were described, and the manifestation of the dimensions of task structure in the task structure diagram were given. Finally, the work of the last two chapters was synthesized and a task design process was described, giving a straightforward approach for designing a military operational scenario based on task structure.

## **IV. SCENARIO DEVELOPMENT FOR THE FIRST A2C2 EXPERIMENT**

### **A. INTRODUCTION**

Chapters II and III focused on enumerating and determining levels of dimensions of task structure, development of a paradigm for visually representing task structure, and stipulation of a process for designing a task based on the dimension of interest and desired structure. This chapter returns to the A2C2 context in which this thesis is written. Recall from Chapter I the original problems of determining the dimension of task structure to be varied, the structural form the task will take, and development of a scenario and variants to fit within those constraints for the initial experiment within the A2C2 project. These issues will be dealt with in this chapter, using the tools developed in Chapters II and III. I will also describe the conduct of that initial experiment, and operationalization of the task and organization structures.

### **B. DETERMINATION OF THE DIMENSION OF INTEREST**

#### **1. Background**

It was stated in Chapter I that the specific dimension of interest for the first experiment with regard to organizational structure was levels of hierarchy, and whether there are circumstances in which a flattened organizational structure would tend to outperform a more hierarchical structure, and vice versa. An issue that arose several times during the A2C2 field research concerned these circumstances. The organizational structure used in the joint officer interviews was relatively "flat," and several of the officers saw reasons to add a layer of hierarchy, typically when one force might need assets that belonged to another (a shared resources dependency under the dimension of coordination requirements, from Chapter II). The extra layer of hierarchy would presumably facilitate coordination when two units were competing over one another's assets. The same question came up in field visits to warfighting commands.

## 2. Research Issue and Hypotheses

Based on the field research and my work in defining dimensions of task structure in Chapter II, the A2C2 team formulated a general research issue: can tasks differ in *coordination requirements* in such a way that an organization structure with more layers is better for some tasks, and a structure with fewer layers is better for others? From that research issue, our general hypothesis developed: there is an interaction between task structure and organization structure, when *coordination requirements* and *levels of hierarchy* are the respective dimensions of interest. More specifically, when two units in the same functional area must coordinate the use of assets in order to process their individual tasks:

- An organization with a common functional commander is better when the assets are owned by one of the two units, whereas
- An organization without a common functional commander is better when the assets are owned outside of the functional area.

The reasoning behind the first assertion is that placing an experienced component commander over all forces in a functional area will focus those forces on a common mission or goal. The subordinate commanders will be more likely to make decisions that are optimal for the component as a whole, and if they do not, the common commander, with his component-centric focus, will be able to mitigate conflicts within the component in a timely manner. The overall commander, on the other hand, is poorly positioned to act as the common commander. He focuses at a higher level, considering the air, ground, and naval context as a whole. He is too busy with command and control of the overall operation to narrow his focus and mitigate conflicts *within* a component in a timely manner.

On the other hand, when a lower level commander in one functional area needs an asset that belongs to the overall commander (or his superiors), and that asset might also be needed by a unit in another functional area, the overall commander must become cognizant of the specific needs within the functional area before he allocates the asset. If the overall commander and the lower level units all share a common operational picture, the overall commander will not, in theory, need component commanders to apprise him

of the seriousness of their respective units' needs before he makes his decision. If lower level commanders have a common operational picture, they presumably should be able to act in a more autonomous manner to achieve the commander's intent and allocate resources among themselves. As a result, the overall commander should be able to increase his span of control and the organization can become "flatter."

### **3. Dimension of Interest**

Based on the above research issue and hypotheses, the task structure dimension of interest was the "competition over shared resources" subcategory of coordination requirements. It was presented at two levels, level one is high internal competition over shared resources (competition over organic assets), level two is high external competition over shared resources (competition over non-organic assets). It was desired that all other dimensions of task structure remain constant. The factors for the final 2x2 experimental design, then, became organization structure (two-tiered hierarchy versus three-tiered hierarchy) and task structure (competition over organic assets versus competition over non-organic assets).

## **C. DESIRED TASK STRUCTURE**

The A2C2 team also had specific ideas about the structural characteristics of the desired task, and levels of other dimensions that would allow for optimum accessibility to the task and organization structure dimensions of interest.

### **1. Formalization**

A high degree of formalization was considered desirable. The researchers wanted there to be a consistent structural form to the task, and replicable events which would occur in each task requiring each team of subjects to compete over the same resources in identical circumstances. Crucial to this requirement was the need for "one-of-a-kind" resources. Normally, any military force has a certain amount of robustness built in — there is generally more than one asset that can perform a given mission. For example, in an aircraft carrier battle group, there are any number of weapons, from aircraft to frigates

to destroyers, which can engage fast patrol boats. However, if that multiplicity of assets had been allowed in this experiment, then each team of subjects would have, in effect, created its own task structure, potentially completing tasks while avoiding the competition that was the point of the experiment.

## **2. Prerequisites**

In spite of the desire for high formalization, the experimental designers wanted the subjects to be free to make some errors, particularly involving the competition events — the subjects needed to be able to make the wrong decision. As such, prerequisites leading up to the competition events tended to be hard, and prerequisites within the competition events themselves tended to be soft. In execution, though, there were exceptions to this rule, which occasionally resulted in the desired competition events not occurring, or occurring in ways that the experimental designers had not anticipated.

## **3. Separability of Maritime and Ground Portions**

The experimental designers envisioned a scenario involving a joint task force (JTF) with two components under the JTF, a maritime component and a ground component, each component further comprised of two lower-level units. Recall from Chapter 1 that the two levels of organizational structure to be tested in this experiment were two-tiered and three-tiered. Although the two-tiered and three-tiered structures were separated for analysis, the two JTF organizations that were used for the experiment each had an intermediate commander supervising one component and none supervising the other. Thus, in half of the runs there was a ground component commander (GCC), while in the other half there was a maritime component commander (MCC), as shown in Figure 4. This was done in order to keep the number of subjects constant across all trials, and avoid task-load-per-individual problems that would have arisen had the two structures been composed of different numbers of subjects.

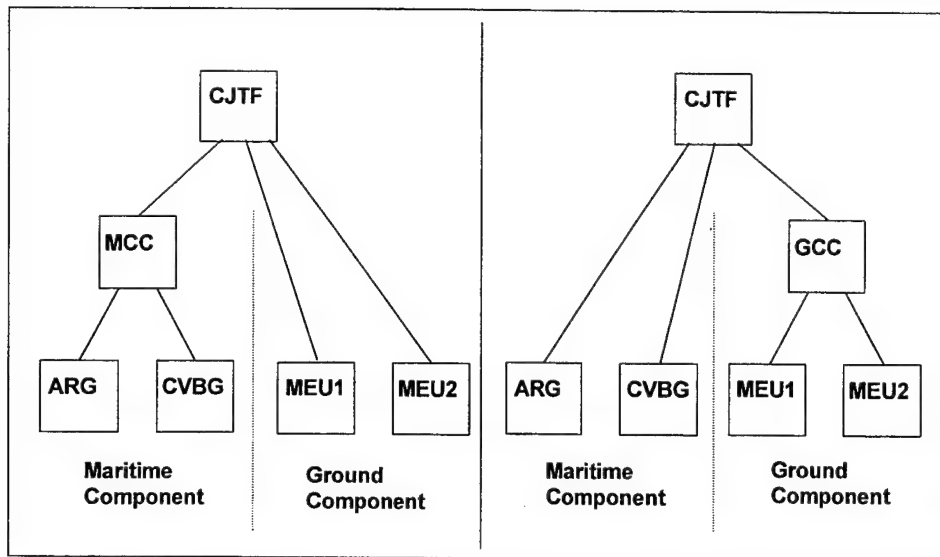

Figure 4. Organizational Structures Used In Experiment

A goal of the design team was for the competition events in the scenario to be modular with regard to the components; competition events should not occur *across* components, but between the two lower level units *within* each component. A *module* was then defined as that portion of a scenario that affected one component. A desired result of this separation of ground and maritime competition events was a potential doubling of the number of data points, since two sets of competition scores per experimental run would then be received. A complete scenario was composed of two modules — one maritime and one ground. The modules were numbered as follows:

- Module 1: Competition Between Ground Units for Organic Assets
- Module 2: Competition Between Ground Units for Non-Organic Assets
- Module 3: Competition Between Maritime Units for Organic Assets
- Module 4: Competition Between Maritime Units for Non-Organic Assets

Modules 1 and 3 were combined to form Scenario 13, competition for organic assets (level one), and Modules 2 and 4 were combined to form Scenario 24, competition for non-organic assets (level two).

The designers further wanted the task structure of the ground and maritime modules to be as similar as possible, within levels; the Module 1 task structure diagram should look like the Module 3 diagram, and Module 2 should likewise resemble Module

4. This proved to be difficult, because of the basic difference in the ground and maritime missions that will be discussed in a later chapter.

#### **D. SCENARIO DEVELOPMENT**

The scenario for the first experiment was adapted from the scenario used for the joint officer interviews (Alphatech, Inc., 1995) . My goal was to design two variants of the same scenario, one to be used as level one (Scenario 13) and the other as level two (Scenario 24), identical except for the competition events.

What follows is a detailed description of the scenarios I developed, including the general situation, enemy situation, friendly forces and asset ownership, mission, how the mission will be executed by friendly forces, friendly force priorities, the manner in which each variation of the scenario should unfold, and the scenarios used for training the subjects.

##### **1. General**

Orange, a North African nation friendly to the United States, is under attack by Green, whose forces have taken control of Orange's port of Eastport. A Joint Task Force (JTF) is organized by a notional theater commander in chief, the Commander in Chief, Mediterranean Command (CINCMED), in order to capture the port and airfield of Eastport to allow for the introduction of follow-on forces. CINCMED's ultimate purpose will be to drive Green forces from Orange and destroy their capability for offensive warfare. The Commander, JTF (CJTF) has at his disposal an aircraft carrier battle group (CVBG), an amphibious ready group (ARG) large enough to transport two Marine Expeditionary Units (Special Operations Capable) (MEU(SOC)), and two separate MEU (SOC)s. Figure 5 gives a representation of the Eastport area.

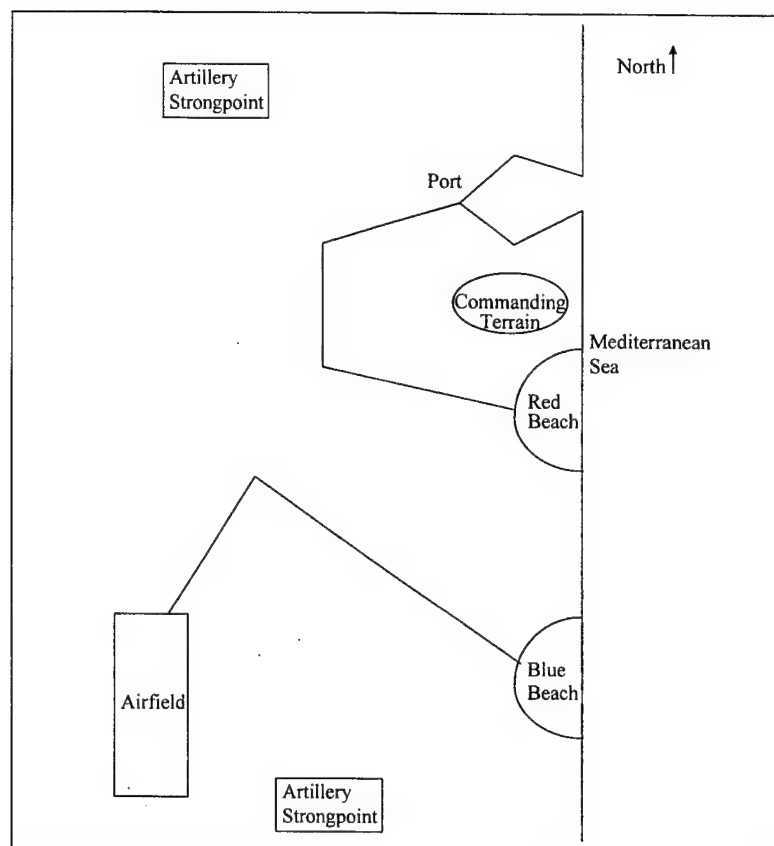

Figure 5. Eastport Area

## 2. Enemy Situation

A heliborne or across the beach assault directly into the port of Eastport would be too risky because of obstructions, mines, obstacles, and the presence of hidden enemy among the port facility buildings armed with handheld surface-to-air missiles. About 5 miles south of the port, there are two suitable landing beaches. There is a road leading from the northernmost beach (designated "Red Beach") to the port, and another leading from the southernmost beach (designated "Blue Beach") to the airfield. The waterborne approaches to the beaches are possibly mined, and a piece of commanding terrain to the north of Red Beach is occupied by an enemy heavy mortar platoon with a platoon of infantry for security. This commanding terrain dominates both Red Beach and the port, and must be taken and held throughout any attack on Red Beach or the port.

Known to be at the port, but hidden from view, is a company-sized mechanized counterattack force that could move toward Red Beach to try to foil any amphibious

assault. It is possible that there is a similar counterattack force at the airfield, which is located about 5 miles inland from Blue Beach. The counterattacking forces could inflict serious damage if they are not interdicted before they arrive at either beach once they begin movement. The off-road terrain between the beaches, port, airfield, and commanding terrain is swampy and treacherous, and is unsuitable for travel. Thus, all travel must be on the two roads. It is suspected that one or both of the roads will be mined, but the locations of any minefields are unknown, and will not be known until friendly units approach them. These "pop-up" minefields must be breached by engineers before the friendly forces can move beyond them.

The port, airfield, both roads, both beaches, and the commanding terrain are located within range of two artillery strongpoints, one about 10 miles northwest of the port, and the other about 10 miles south of the airfield. The northernmost strongpoint can range Red Beach and the port, and the southernmost strongpoint can range the airfield and Blue Beach. Both are within range of two Naval Surface Fire Support (NSFS) stations off the port — one in support of MEU 1, and the other in support of MEU 2. The artillery pieces at both strongpoints are housed in reinforced concrete bunkers, and the ammunition stored in deep underground bunkers, so it is unlikely that even concentrated air attacks by the assets under the JTF's control will completely disable the artillery strongpoint. When the enemy wants to fire an artillery barrage, they wheel out the artillery pieces, set them up, and fire within 15 minutes. If friendly forces can get effective NSFS on target in less than 15 minutes, the enemy will wheel their artillery pieces back into their bunkers and wait until another time.

The enemy also has several FROG surface-to-surface missile launchers, known to be capable of carrying chemical munitions, hidden in the vicinity of both artillery strongpoints. They can emerge from their covered positions, prepare their warheads, and fire their missiles within 30 minutes. Past experience has shown that the FROG crews are more stalwart than their artillery comrades — they will continue to prepare and launch their missiles even if they are being suppressed by NSFS. Close air support (CAS) aircraft with precision guided munitions are the only weapons in the JTF's possession that are highly effective against this target, if the aircraft can arrive in time.

At sea, the enemy submarine threat is considerable. The Green forces have one Alfa-class submarine known to be in the area, and one more possible. They possess MI-24 Hind helicopters and strike aircraft as well, both of which have demonstrated the capability to launch anti-ship missiles.

The only surface threat that friendly naval forces face is that posed by the Green navy, which possesses numerous fast patrol boats. These fast patrol boats can either fire very potent Russian torpedoes or be loaded with explosives for suicide missions.

Finally, there are two suspected Silkworm anti-ship missile launchers: one in the city of Eastport itself and the other in a southern residential district. These Silkworm launchers were placed in residential neighborhoods by the Green forces because they knew U.S. planners would be reluctant to target these areas. Accordingly, if the CVBG or ARG wish to target a Silkworm launcher, they must first get visual confirmation of its presence, using theater SR-71 assets, and any strike must use CAS with precision guided munitions in order to minimize collateral damage.

### **3. Friendly Situation and Asset Ownership**

The JTF exists within the structure of the Mediterranean Command (MEDCOM). There is a theater-level Joint Force Air Component Commander (JFACC) and other friendly forces operating against the enemy in Orange, but not in concert with the JTF. The only aircraft from the CVBG available to support the JTF are one section of FA-18s with laser guided bombs to attack FROG launchers, another designated to attack confirmed Silkworm missile sites, and enough combat air patrol (CAP) aircraft, used for anti-air warfare, to man two CAP stations, one above the CVBG and the other above the ARG. All other CVBG assets will support the theater JFACC, and will be unavailable for JTF use. The CVBG will control an aircraft carrier, an AEGIS cruiser which is only capable of performing anti-air warfare (AAW) functions, and a frigate which can only be used for antisubmarine warfare (ASW). The ARG will control two destroyers in position to provide NSFS against either artillery strongpoint (incapable of performing ASW or AAW), several amphibious ships with the MEUs embarked, and one Stinger platoon

detached from one of the MEUs capable of providing close in air defense against helicopters (the only asset in the JTF so capable).

MEU 1 is composed of one Advanced Amphibious Assault Vehicle (AAAV) mounted infantry company, one V-22 Osprey mounted heliborne infantry company, one division (4) of AH-1W Cobra attack helicopters (indivisible), and one V-22 mounted engineer platoon. MEU 2 is composed of one AAAV mounted infantry company, one V-22 mounted heliborne infantry company, and 2 MEDEVAC helicopters (also indivisible). MEU 1 has the Cobras and Engineers because it is considered probable that the port will be more heavily defended by mechanized assets and minefields than the airfield. Each MEU will be considered to have a unmanned aerial vehicle (UAV) flying in its support for the duration of the operation. The players will not control the UAVs but their presence will be represented by the nearly omniscient battlefield picture each MEU will possess.

The CJTF controls the two sections of CAS aircraft previously mentioned, one mine countermeasures (MCM) helicopter embarked aboard the ARG which can clear mines if they are detected, a section of SH-60s armed with Penguin missiles aboard the carrier to be used against any small patrol boats that threaten JTF forces (anti-surface warfare (ASUW)), and a V-22 mounted heliborne infantry company aboard the ARG. This heliborne infantry company is the JTF reserve. In addition, there is a possibility of obtaining JFACC air defense assets from Sicily at the CJTF's request in the event that the carrier-based fighters become unavailable, and a SR-71 is constantly in orbit, in general support of the theater commander-in-chief, that can be requested by the CJTF for any immediate imagery requirements.

As mentioned previously, the assets were designed unrealistically as one-of-a-kind assets, in which only a single asset can accomplish a task in any given situation, in order to induce competition where the experimental designers wanted it to occur. Additionally, the "non-organic" assets were placed under the CJTF rather than the MCC or GCC, although it would have been more realistic, in some circumstances, to place the assets at the intermediate level of hierarchy when present. This was done for consistency; the experimental designers wanted to hold the resource structure constant. A

summary of the assets available, owners, and the threats that can be destroyed or tasks handled by each asset is as shown in Table 3.

Asset	Owner	Task(s) Asset Can Accomplish
Heliborne Infantry Company	MEU 1 MEU 2 CJTF	Attack Enemy Positions & Ground Forces, Hold Positions
AAAV-Mounted Infantry Company	MEU 1 MEU 2	Attack Enemy Positions & Ground Forces, Hold Positions
Engineer Platoon	MEU 1	Clear Mines on Land
AH-1W Cobra Helicopters	MEU 1	Enemy Tanks
MEDEVAC Helicopters	MEU 2	Perform Medical Evacuation
Frigate	CVBG	Perform ASW
AEGIS Cruiser	CVBG	Perform AAW
F-14 CAP	CVBG ARG	Perform AAW
Destroyer	ARG	Provide NSFS Against Artillery
Stinger Platoon	ARG	Perform AAW Against Helicopters
SH-60 Helicopters	CJTF	Perform ASUW
CAS Aircraft	CJTF	Destroy FROG & Silkworm Launchers
F-15 CAP	CJTF	Perform AAW
SR-71	CJTF	Identify Silkworm Launchers
MCM Helicopters	CJTF	Clear Mines from Beach

Table 3. Assets, Ownership, and Capabilities

The DDD-III implemented the asset-to-task matchings via specification of task resource requirements and asset resource capability. To each task (and asset) there was associated a 7-dimension resource vector  $R = [r_1, r_2, \dots, r_7]$  with components that correspond to combat capability/potential, or task requirements in various categories. For example,  $r_1$  = air combat,  $r_2$  = sea combat, ...,  $r_5$  = mines,  $r_6$  = holding/occupying,  $r_7$  = medivac. By giving a specific task a set of values for  $R$  the DDD-III establishes what (mix of) assets with their corresponding  $R$ s suffice to correctly process that task. Thus, mine-clearing helicopters would have values for  $r_5$  corresponding to those required for mine clearing tasks, but other assets would have lower values for  $r_5$ , or zero (Kemple, et al., 1996a).

#### **4. Mission**

Ground Component: To secure the port and airfield of Eastport, to allow for the introduction of follow-on forces.

Maritime Component: To support the amphibious operation with close air support, naval surface fire support, mine countermeasures, and air defense assets, and to defend the CVBG and ARG from air, surface, and subsurface threats.

#### **5. Execution**

Each MEU will simultaneously land its AAV-mounted company on the beach. MEU 1 will attack Red Beach, and MEU 2 will attack Blue Beach. MEU 1 will simultaneously secure the commanding terrain overlooking Red Beach and the port with its heliborne company. Once the beaches and commanding terrain are secure, the two AAV-mounted companies will proceed down the roads from their respective beaches, clearing minefields with the engineer platoon, killing counterattack forces with the Cobras, and conducting MEDEVACs as necessary.

Each MEU will have a UAV (launched from the ARG) airborne for the duration of the operation. The UAVs will keep the artillery strongpoints and the suspected FROG sites under constant surveillance, so that NSFS or CAS assets can be brought to bear immediately if they are needed. The section of CAS aircraft earmarked for use against FROG launchers will be on 5 minute strip alert aboard the aircraft carrier.

Once the roads have been cleared, the AAV-mounted companies from MEU 1 and MEU 2 will attack the port and the airfield, respectively. MEU 2's AAV-mounted company will be joined in its attack by a heliborne company from MEU 2. It is important that, once the AAV-mounted companies land on the beach, the airfield and port be taken as quickly as possible, before the enemy has a chance to organize his defense and send reinforcements. It is desired that final assaults on the airfield and port be conducted simultaneously, in order to present the enemy commander with the most confusing, dilemma-filled environment possible, but, if one attack must be conducted before the other, the airfield takes priority. If the airfield attack is held up for any reason, the port

attack should wait to retain the synergism of concurrent attacks; if the port attack is held up, the airfield attack should go forward. The CJTF's reserve infantry company can be requested by whichever MEU needs it at any point during the operation, in case either the port or the airfield are too well defended for MEU 1 or MEU 2 to be able to secure them with the forces available.

Due to hydrographic limitations, the ARG and the CVBG will have to be significantly separated during the operation, enough to preclude them from being under a joint air defense umbrella provided by the AEGIS cruiser. Thus, the AEGIS cruiser will remain with the CVBG, but will position itself so that it can rapidly move from the CVBG to the ARG if that becomes necessary. Additionally, the two destroyers will be inshore, providing NSFS support, while the frigate is the primary anti-submarine warfare platform for the CVBG. The frigate performing anti-submarine warfare will, like the AEGIS cruiser, position itself so that it can quickly move to support the ARG if that is necessary. Any assets supporting the ARG must be under the control of the ARG, and assets supporting the CVBG must be under the control of the CVBG.

The ARG will launch the aforementioned three companies of Marines for the initial assault on Red and Blue Beaches. The ARG will launch the mine countermeasures helicopters, Cobras, MEDEVAC aircraft, the air assault for MEU 2's attack on the airfield, and the CJTF reserve when called to do so. The ARG will also, with its destroyers providing NSFS, suppress the artillery strongpoints ashore when requested to do so by either of the MEUs.

The CVBG will keep two sections of FA-18s with precision guided munitions on standby at all times: one to be used against FROGs (in support of the MEUs), and the other against Silkworms (in support of the CVBG or ARG). The CJTF will be launch authority for both sections. The CVBG will also provide 2 sections per hour of air defense aircraft (FA-18 or F-14), with one CAP station over the CVBG and the other over the ARG.

If the CVBG or ARG encounters a surface threat, then it must request the SH-60s from the CJTF in order to deal with that threat. If a suspected Silkworm launcher is detected, then it must be identified first by the SR-71 before it can be destroyed. A

Silkworm launcher detected at the northernmost site threatens the CVBG; at the southernmost site, the ARG.

## **6. Priorities**

The JTF's overall priority, and the priority within the ground component, is MEU 2's attack on the airfield, because buildup of friendly forces can be most quickly and effectively achieved through air transport.

The following was given to the subjects as the CJTF's priorities within the maritime component: if both the ARG and CVBG are threatened by the enemy, the ARG has priority of support against submarine threats, fixed-wing air threats, and patrol boats. If there is a threat of an air attack against the ARG, the ARG should get the AEGIS cruiser and a CAP. The frigate performing anti-submarine warfare and the AEGIS cruiser stay with the CVBG unless a necessity occurs with the ARG, however, because the CVBG is considered a more likely target for the enemy. The CVBG has priority against land-based Silkworm sites and helicopters. The Stinger platoon will remain on the ARG, however, because it is considered a more likely target for enemy helicopters, since the only known enemy helicopter bases are closest to the ARG, and will only transfer to the CVBG if there is evidence of an imminent attack. To expedite this transfer, should it become necessary, the Stinger platoon will have V-22 helicopters at its disposal.

## **7. Scenario 13, Competition Over Organic Assets**

In Scenario 13, the ground component (MEU 1 and MEU 2) competed for MEU 1's engineer platoon and Cobras and MEU 2's MEDEVAC helicopters. The maritime component (ARG and CVBG) competed over the ARG's Stinger platoon and the CVBG's AEGIS cruiser, frigate, and section of CAP aircraft. Non-organic assets that were not competed over, but were used, were the reserve heliborne company, mine countermeasures helicopter, JFACC CAP aircraft, the SH-60s, the SR-71 mission, and the CAS aircraft to be used against Silkworms and FROGs. These non-organic assets were competed over in Scenario 24.

On the ground side, the scenario started with MEU 2 detecting mines as it approached the beach. MEU 2 should have immediately requested the mine countermeasures helicopter to clear the mines. Once the mines were clear, the air assault on commanding terrain and the AAV assaults on Red and Blue Beaches then occurred concurrently. After the AAV-mounted companies had taken the beaches and began moving down their respective roads, enemy tanks were observed moving down both roads towards Red and Blue Beaches. MEU 1 and MEU 2 competed for the Cobras — since MEU 2 had priority, the correct response would be for MEU 2 to use them first. Parallel with the assault, the enemy artillery from the northern strongpoint was observed coming out of its bunkers by MEU 1, which should have called NSFS to suppress it. The artillery would emerge from its strongpoints about every five minutes throughout the scenario to threaten alternately MEU 1 and MEU 2. This was not used as a competition event, but as “busywork” to ensure the players had enough to do.

Soon after the tanks appeared, friendly casualties were incurred at both beaches. MEU 1’s casualties were most severe, so the correct response was for MEU 2 to give their MEDEVAC helicopters to MEU 1.

After the enemy tanks were dealt with, MEU 1 and MEU 2 could begin moving down their respective roads toward their objectives. They then simultaneously encountered minefields on the roads — MEU 2 had priority, so the correct response was for MEU 1 to give its engineer platoon to MEU 2. At about the same time as MEU 1 was clearing its mines, a FROG launcher emerged from hiding, observed by MEU 2’s UAV. MEU 2 should then have requested the standby CAS section to attack the FROG launcher. MEU 2, meanwhile, should have begun conducting its coordinated attack on the airfield.

After MEU 1 finished clearing its mines, it should have attacked the port. As it approached the port, the MEU 1 commander realized that the enemy’s strength at the port was greater than he expected. He needed to call for the reserve company before he could attack. Upon completion of MEU 1’s attack, the ground objective was achieved. A task structure diagram depicting Module 1 is given in Figure 6.

On the maritime side, shortly after the detection of the mines in front of Blue Beach, submarines were detected, one moving toward the ARG and the other toward the CVBG. The correct response was for the CVBG to give its frigate to the ARG. At the same time, two sections of CAP aircraft launched from the carrier, one for the CAP station above the CVBG, and the other for the CAP station over the ARG. They remained on station for one hour.

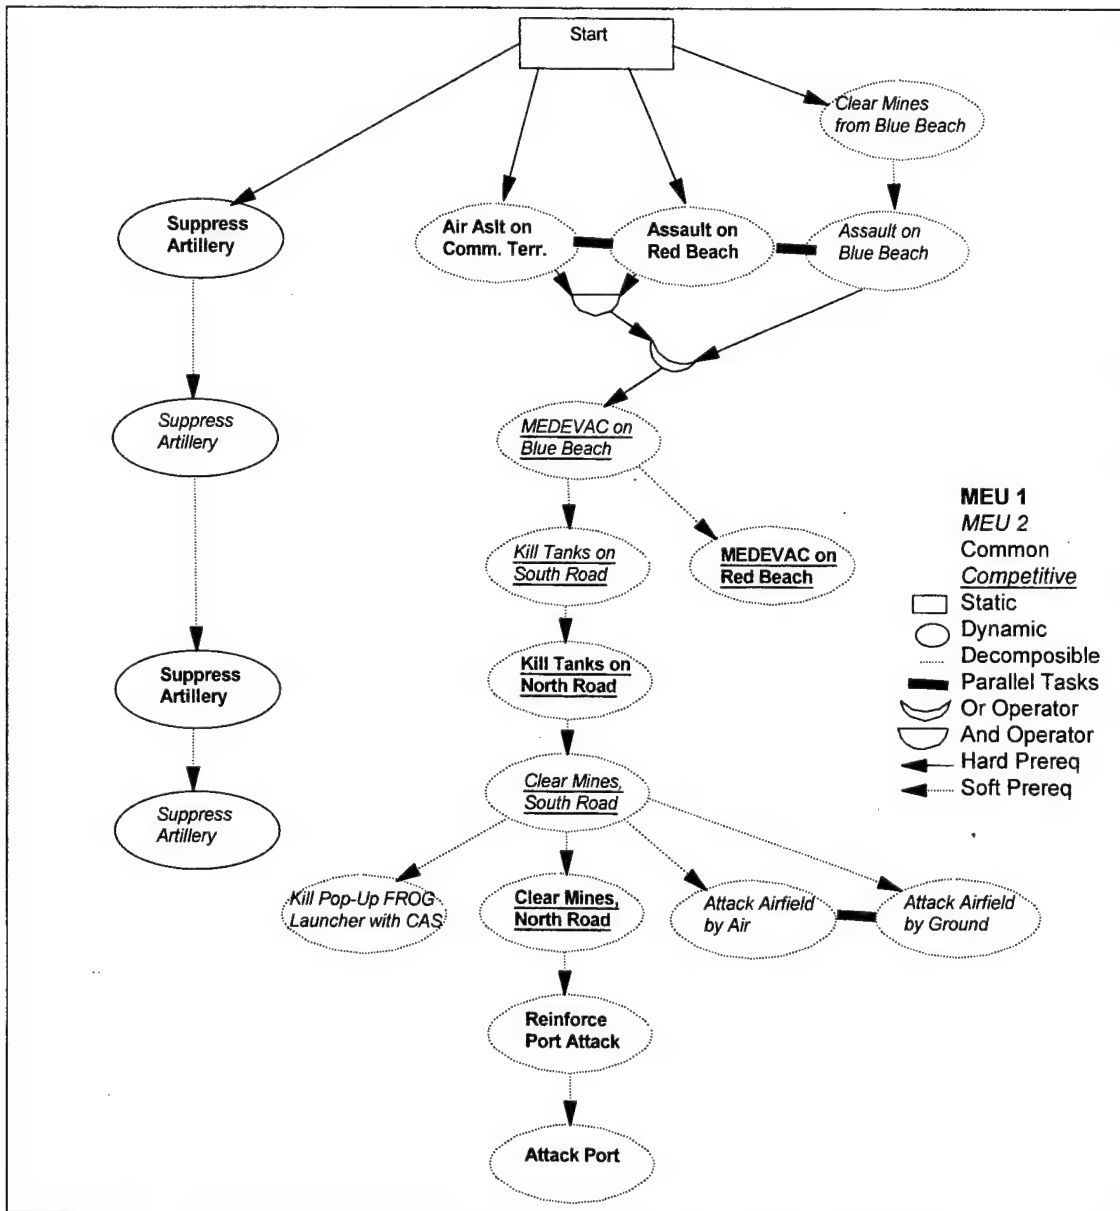

Figure 6. Module 1: Competition Between Ground Units for Organic Assets

Soon afterward, and after the MEUs' assault on Red and Blue Beaches, Green Hind helicopters with antiship missiles were detected preparing to take off from two airfields, one within range of the CVBG and the other within range of the ARG. The correct response was for the ARG to transfer its Stinger platoon to the CVBG, since the CVBG had priority. After this, and concurrently with the clearing of the minefields in the roads ashore, two things happened. First, fast patrol boats were detected approaching the CVBG. The CVBG should have requested the SH-60s from the CJTF to destroy this threat. Also, an intelligence report of a fixed-wing air attack preparing to take off against the ARG was received from the theater commander-in-chief. The correct response was for the CVBG to transfer the AEGIS cruiser to the ARG. Also at the same time, both CAP aircraft ran out of fuel, and returned to the carrier. Only one relief section was available — belonging to the CVBG. This should also have been diverted to the ARG, because the ARG had priority. Soon afterward, if requested, a section of JFACC F-15s from Sicily came out to support the CVBG.

Next, a report was received of a Silkworm site in the north, threatening the CVBG. The CVBG requested SR-71 overflight to confirm the missile site, then requested launch of the FA-18s with precision guided munitions to destroy it. Figure 7 is a task structure diagram depicting the Module 3 task.

#### **8. Scenario 24, Competition Over Non-Organic Assets**

In this scenario, the organic and non-organic assets were the same as in Scenario 13; however, the organic assets were not competed over, and the non-organic assets were. Scenario 24 unfolded as did Scenario 13, except for the following:

On the ground side, both MEUs simultaneously detected mines as they approached the beach. Since MEU 2's attack had priority, the correct response was for the CJTF to give MEU 2 the mine countermeasures helicopters first. Each assault began immediately after the mines were cleared from its respective beach. Once the MEUs landed on the beaches, the enemy tank column and mines only appeared on the north road, threatening MEU 1. There was no competition for the engineers and Cobras. Casualties were only incurred by MEU 2, so there was no competition for the

MEDEVAC helicopter. FROG launchers, however, were detected simultaneously by both MEU 1 and MEU 2, causing competition over the CAS aircraft. Since MEU 2 had priority, the correct response was for MEU 2 to get the CAS aircraft first. Finally, as the MEUs approached their objectives, it became clear that neither would be able to take its objective without reinforcements, so there was competition over the JTF reserve. The correct response was for MEU 2 to get the reserve first, then MEU 1. Figure 8 depicts Module 2.

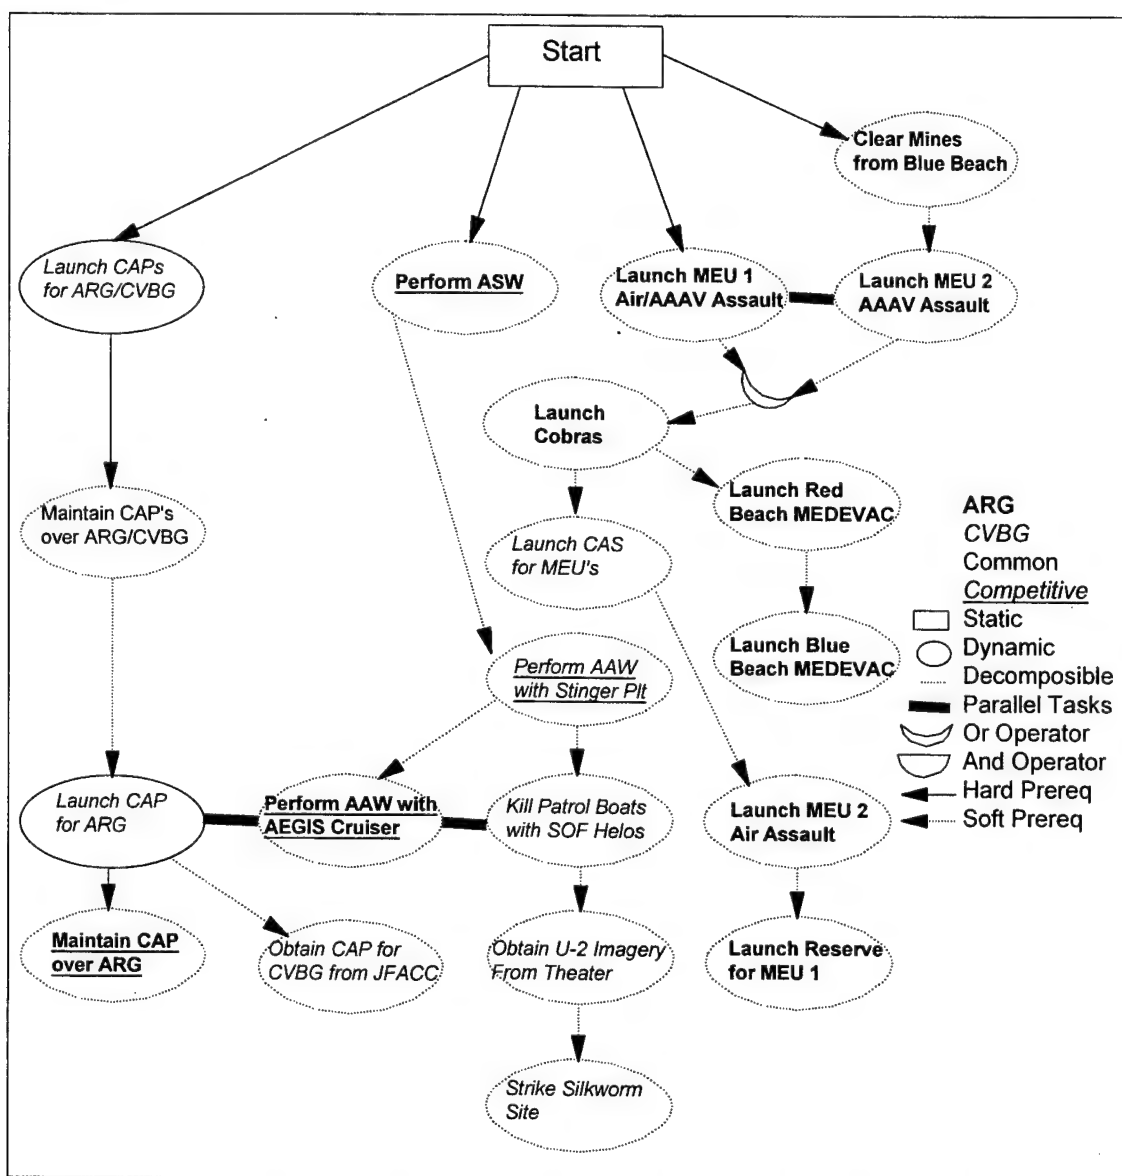

Figure 7. Module 3: Competition Between Maritime Units for Organic Assets

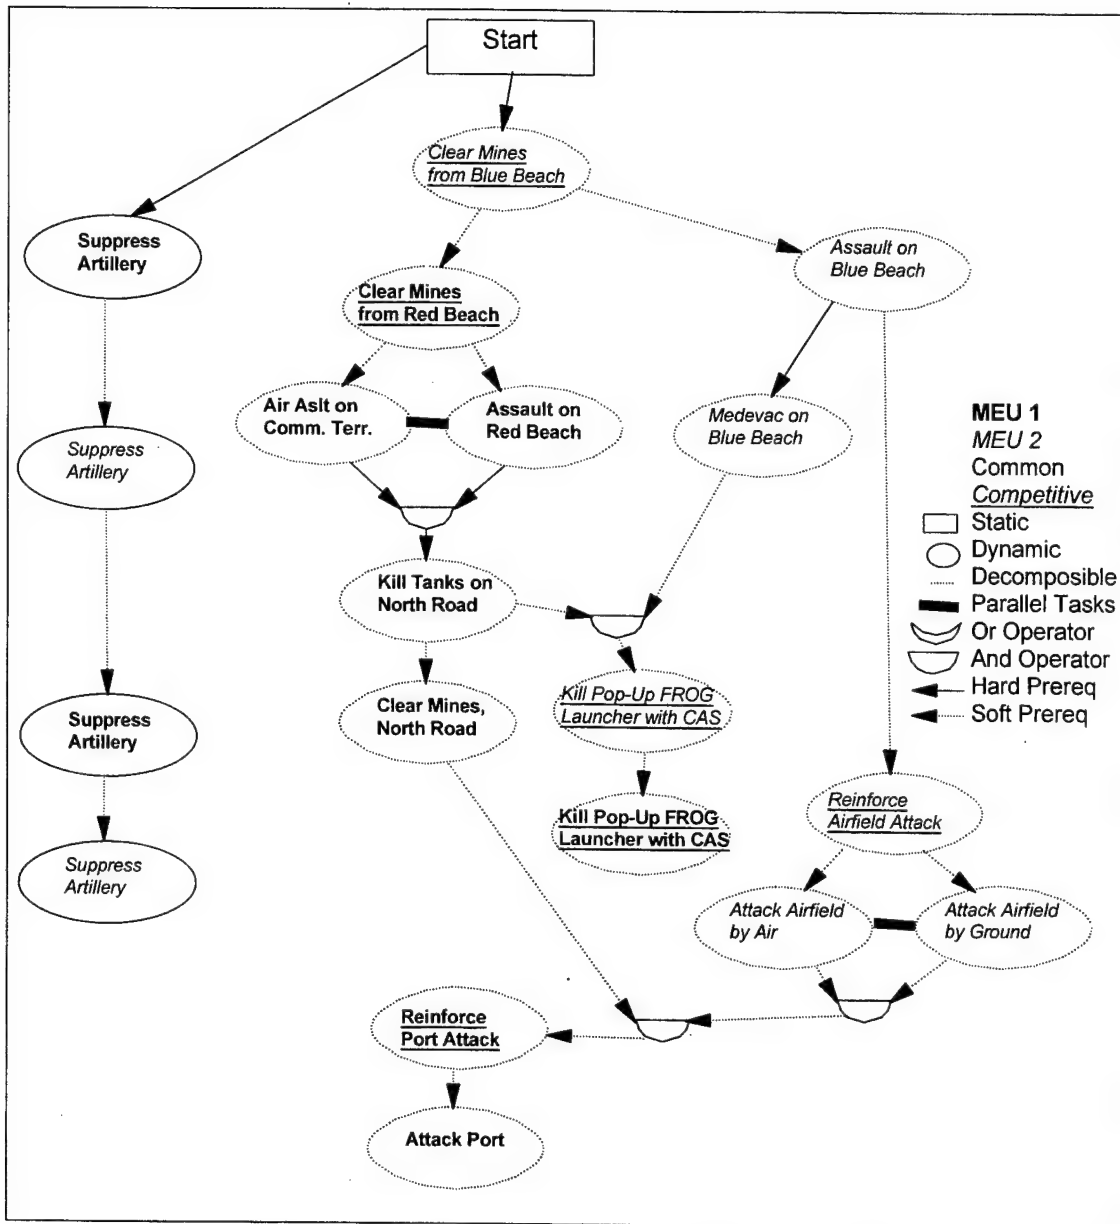

Figure 8. Module 2: Competition Between Ground Units for Non-Organic Assets

On the maritime side, the enemy submarine was detected moving toward the CVBG instead of both the CVBG and the ARG, eliminating the competition over the frigate. The enemy helicopters detected preparing to take off were only within range of the ARG, not the CVBG, eliminating the competition over the Stinger platoon. There were reports of two Silkworm sites instead of one, however, one threatening the CVBG and the other threatening the ARG. This caused competition over the SR-71 and CAS. Here, the SR-71 flyover should have been requested first for the CVBG and then for the

ARG. Both sites were confirmed (simultaneously), and the CVBG should have gotten the FA-18's first, and then the ARG. The report of the air attack was only against the CVBG, eliminating the competition over the AEGIS cruiser. Also, no CAP aircraft at all were available for the second coverage period; the ARG and CVBG then competed over a section of CAP aircraft that became available almost immediately from the JFACC. The correct response was for the ARG to get the JFACC CAP, because the air attack was over and it the ARG had priority. Finally, fast patrol boats were detected moving toward both the ARG and CVBG, inducing competition over the SH-60s. The correct response was for the CVBG to get the SH-60 assets. Module 4 is depicted in Figure 9.

## **9. Development of Training Scenarios**

In order to familiarize the subjects with the general situation in the scenarios, the DDD III simulator, the operational context, and activities required such as transferring assets back and forth, requesting assets, communicating using preformatted message sets, et cetera, I created training scenarios based on the experimental scenarios. The training scenarios were identical to the experimental scenarios, except that they did not contain any competition events. I developed two training scenario variants, each composed of a ground and a maritime module, and designed them so that each lower level unit had an opportunity to perform each subtask and use every asset. For example, if, in one training scenario, MEU 1 killed tanks with its Cobra helicopters, then, in the other training scenario, MEU 1 transferred the Cobras to MEU 2 to destroy tanks. The specific training scenarios are described below.

### ***a. Training Scenario 13***

MEU 2 detected mines as it approached Blue Beach, and had to clear them. After the mines had been cleared, MEU 1 and MEU 2 continued their coordinated attack on the commanding terrain, Red Beach, and Blue Beach. Once the beaches were secure, MEU 2 encountered tanks on the south road, and needed to request MEU 1's Cobras. MEU 1 then needed to MEDEVAC casualties, and requested MEU 2's

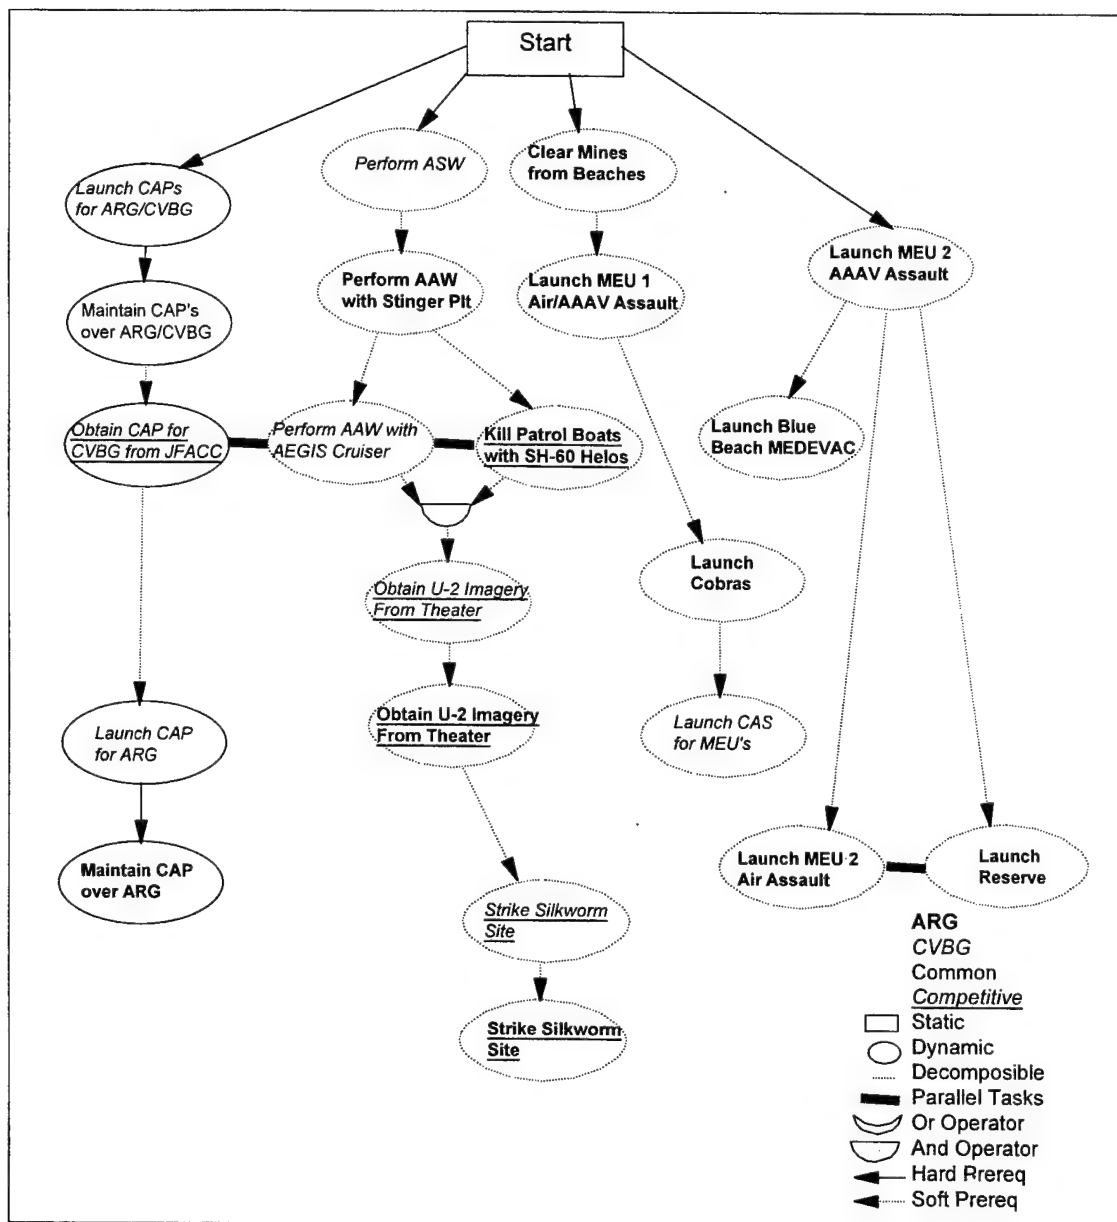

Figure 9. Module 4: Competition Between Maritime Units for Non-Organic Assets

MEDEVAC helicopter. Subsequently, MEU 1 encountered mines on the north road, and cleared them with their own engineer platoon.

Meanwhile, MEU 2 detected a FROG launcher, and needed to request CAS from the CJTF. After MEU 1 cleared its mines, it continued the attack and realized that it needed reinforcements in order to capture the port. MEU 1 then requested the reserve from the CJTF. When MEU 2 reached the airfield, it conducted a coordinated attack with its AAV company and its heliborne company.

Throughout the training scenarios, artillery targets popped up, and either MEU 1 or MEU 2 needed to request NSFS from the CJTF in order to suppress the targets.

On the maritime side, the ARG was threatened by a submarine, and requested the frigate from the CVBG. Meanwhile, CAPs were launched and maintained above the ARG and CVBG. Only the ARG was threatened by a helicopter attack, and used its own Stinger platoon to defend itself. Then, an inbound air attack was reported, but only threatened the CVBG, which defended itself with the AEGIS cruiser and requested a section of CAP from the JFACC (via the CJTF), its own CAP having run out of fuel by then with no others available. At the same time, patrol boats were observed heading toward the CVBG, which requested the SH-60's from the CJTF in order to defend itself. Finally, the ARG was threatened by a Silkworm launcher, and needed to request the SR-71 imagery and a section of CAS from the CJTF in order to destroy the launcher.

***b. Training Scenario 24***

This was identical to Training Scenario 13, but "who needed which asset" was reversed. MEU 1 needed the mine countermeasures helicopter and CAS from the CJTF, and needed to use its own Cobras, while MEU 2 will needed to request the reserve company from the CJTF and the engineer platoon from MEU 1, and used its own MEDEVAC helicopters.

On the maritime side, the CVBG needed to request the SR-71 imagery and CAS from the CJTF and the Stinger platoon from the ARG, and used its own anti-submarine warfare asset. The ARG had to request the JFACC CAP and the SH-60s from the CJTF, and the AEGIS cruiser from the CVBG.

**E. GRADING DIMENSIONS OF TASK STRUCTURE IN SCENARIOS**

The final step in the task design process, after drafting the scenarios that differ in the task structure dimension of interest and comply with the desired task structure, is to grade the dimensions of task structure in order to ascertain whether they differ and are

held constant in the right dimensions. Below Modules 1 and 2 are compared against each other, as are Modules 3 and 4.

## **1. Modules 1 and 2**

### ***a. Uncertainty***

The main issues of uncertainty that occur in both modules are the location of the tanks, the location of the offshore mines and mines on the road, the enemy strength at the port and the airfield, which FROG launchers and artillery will pop up and when, and the location, timing, and priority of MEDEVACs. These are the same across both modules, so uncertainty in Modules 1 and 2 is constant, and graded as Medium.

### ***b. Time Pressure***

Time pressure varied across subtasks within modules, but was constant across the modules, since subtasks carried the same time pressure scores in one module as they did in another. This should be classified as Medium overall, for both modules.

### ***c. Complexity***

Since complexity is not the dimension of interest in this experiment, it is not necessary to decompose it into its five characteristics and score each characteristic. The attributes, paths, outcomes, interdependence of outcomes, and probability of linkages were all basically the same for both modules. This was true because the modules both involved the same subtasks and actions — the difference was in which subtasks were performed twice. In Module 1, the subtasks which involved competition over organic assets were performed twice, while in Module 2, the subtasks which involved competition over non-organic assets were performed twice. Those subtasks were quite similar in complexity and level of effort, so an overall score for comparison purposes is sufficient. Both Modules 1 and 2 are of Medium complexity.

**d.      *Coordination Requirements***

Coordination requirements was the task structure dimension of interest for this experiment. The grading of each of the types of dependencies present is as follows:

(1) Shared Resources. As previously discussed, the shared resources dependency was varied in Modules 1 and 2. In Module 1, the grade for competition over internal shared resources is High, and the grade for competition over external shared resources is None. In Module 2, the grade for competition over internal shared resources is None, and the grade for competition over external shared resources is High.

(2) Producer/Consumer Relationships. Although there are more solid arrows (indicating hard prerequisites) on the Module 1 diagram (Figure 4) than on the Module 2 diagram (Figure 6), the number of subtasks that are affected by these solid arrows is in both cases seven. This dependency is graded as Medium for both modules.

(3) Simultaneity Constraints. This dependency is also graded as Medium for both modules. Although, in Module 1, the Assault on Blue Beach subtask was required to be conducted in concert with the Assault on Red Beach and Air Assault on Commanding Terrain subtasks, while only the latter two subtasks were conducted in concert in Module 2, the additional coordination required for that parallelism was negligible.

(4) Task/Subtask. The task/subtask dependency is not present in either module. The scenarios were given to the players in "prescribed" form, to a large degree, and there was no requirement for tasks to be subdivided among actors.

**e.      *Magnitude***

Magnitude is also constant across tasks. Both Modules 1 and 2 contain 20 subtasks each, and most of these subtasks are the same in both tasks. The difference, as with complexity, is in which subtasks are performed twice. The subtasks performed twice

in Module 1, Conduct MEDEVAC, Kill Tanks, and Clear Mines, require a total of 12 actions per pair of subtasks. The subtasks performed twice in Module 2, Clear Mines from Beaches, Kill FROG Launchers, and Reinforce Attacks, also require a total of 12 actions per pair of subtasks. Thus, the subtasks are equivalent, since they all require the same number of actions, so the tasks would each be scored as 20 on a "subtasks" scale.

***f. Resources Required***

Module 1 and Module 2 each require 19 resources to complete all subtasks, so resources required is constant across tasks.

***g. Information Required***

Module 1 and Module 2 each require 21 separate pieces of information to complete all subtasks, so information required is also constant across both tasks.

***h. Task Formalization***

Both Module 1 and Module 2 are High formalization. The subtasks that must be completed for both tasks are well defined and well structured, and there are clear paths to the correct solution.

***i. Dynamicity***

Dynamicity is High for both tasks. Almost all subtasks within both modules would change over time.

**2. Modules 3 and 4**

***a. Uncertainty***

Uncertainty in Modules 3 and 4 is Medium, as in Modules 1 and 2. The uncertainty issues that occur in Modules 3 and 4 are the number and target of attacking submarines, the number and target of fixed wing and rotary wing air attacks, the number and location of Silkworm launchers, and the number and target of attacking patrol boats.

**b. Time Pressure**

The time pressure characteristics were the same for Modules 3 and 4 as they were for Modules 1 and 2, and is graded as Medium for both modules.

**c. Complexity**

Complexity circumstances were the same for these modules as they were for Modules 1 and 2. Complexity is graded as Medium for Modules 3 and 4 as well.

**d. Coordination Requirements**

(1) *Shared Resources*. This is the same as it was for Modules 1 and 2. In Module 3, the grade for competition over internal shared resources is High, and the grade for competition over external shared resources is None. In Module 4, the grade for competition over internal shared resources is None, and the grade for competition over external shared resources is High.

(2) *Producer/Consumer Relationships*. There are six solid arrows in both the Module 3 and Module 4 diagrams, indicating 6 producer/consumer relationships between subtasks within each task. This dependency is graded as Medium for both modules.

(3) *Simultaneity Constraints*. This dependency is also graded as Medium for both modules. There are a total of three solid bars indicating parallel activities in each of the two modules.

(4) *Task/Subtask*. As was true in Modules 1 and 2, the task/subtask dependency is not present in either of these two modules.

**e. Magnitude**

Magnitude is again considered constant over both Modules 3 and 4, although Module 3 has 21 subtasks and Module 4 has 22. The difference occurred

because two of the competition events in Module 4, Identifying and Striking Silkworm Sites, required the subtasks to be performed twice, while all the other competition events in these two modules were only performed once. However, the first subtask in a two competitive subtask chain, such as the two "Strike Silkworm Site" subtasks in Module 4 and all the competitive subtasks in Modules 1 and 2, requires twice as many actions as the second subtask in the chain, because the first subtask is where the recognition and resolution of the competition actually occurs. The second subtask in the chain, performing the lower-priority subtask, is merely a "push-button" subtask, requiring little decisionmaking skill. Thus, adding an extra subtask in Module 4 was considered of relatively little significance.

***f. Resources Required***

Module 3 and Module 4 each require 20 resources to complete all subtasks, so resources required is constant across tasks.

***g. Information Required***

Module 3 and Module 4 each require 24 separate pieces of information to complete all subtasks, so information required is also constant across both tasks.

***h. Task Formalization***

Modules 3 and 4 contain the same characteristics as Modules 1 and 2, and are also graded as High formalization.

***i. Dynamicity***

Dynamicity is again High for both tasks. Almost all subtasks within both modules would change over time.

## **F. CONDUCT OF EXPERIMENT**

### **1. Experiment Setup**

#### ***a. Physical***

The six test subjects for each team were presented the scenario on a distributed, interactive, computer simulation running on seven SUN SPARC<sup>TM</sup> workstations. (The seventh station was the experimenter's station.) The facility used was the Systems Technology Laboratory at the Naval Postgraduate School in Monterey, CA. Although all subjects were in the same room, dividers were placed between them, and (to facilitate subsequent data analysis) communications among subjects was restricted to preformatted computer messages built into the simulator.

#### ***b. Lead Team***

A group of eight NPS officer students from the Joint C4I Systems, Space Systems Operations, and Operations Research curricula were designated as the "lead team" for this experiment. Three of the members of the lead team were so designated because their theses involved the experiment; the other five were enrolled in CC4103, "Evaluation of Command and Control Systems," a required course in the Joint C4I Systems curriculum, of which the conduct of this experiment was an integral part. The lead team was composed of officers from all four branches of the armed forces, and all members had recent operational experience. The author headed the lead team.

The lead team performed such tasks as preparation of training materials for the subjects, conduct of subject training, setup of the physical space, debugging the simulator and the scenario's implementation in the simulator, conduct of the experimental runs, and data collection. The lead team also provided invaluable suggestions and advice concerning all of the above subjects as well as scenario development, and filled many gaps in the author's experience.

*c. Test Subjects Used*

The test subjects were 24 military officer students from the Joint C4I Systems curriculum at NPS. The subjects were organized into four six-person teams. The teams were formed by the experimenters with participants distributed according to military occupational/warfighting specialty and branch of service, to the extent that that was possible given the demographics of the sample.

Since there was a fairly significant difference between the operational experience of the subjects, the experimenters were concerned that some subjects would be more familiar than others with the appropriate tactics to employ in a given situation, and that this might have an undesirable effect on the performance measures chosen as dependent variables. In order to counter such an impact, the scenarios and the operations order were tailored to facilitate a "cookbook" approach to each situation. This approach further aided the experimenters' attempt to steer the subjects toward the competition events that were of primary interest in the experiment.

*d. Simulator*

The experiment was conducted using the Distributed Dynamic Decisionmaking-III (DDD-III) simulator. Earlier variants of the DDD had been used extensively in the past to study decisionmaking in the Navy's Composite Warfare Commander (CWC) organizational structure. In a concomitant effort, the DDD was extended to fit the general requirements of tier-I experimentation for the A2C2 project, and was adapted to meet the specific requirements of the current experiment. Although it is not a tactical model on the level of RESA, JTLS, MTWS, CBS, or AWSIM, it contains data collection and variable manipulation capabilities that make it very appropriate for a research environment. For a more detailed treatment of DDD-III, its characteristics, and implementation in DDD-III of the scenarios and organizational structures used in this experiment, see Higgins (1996).

*e. Matching of Subjects to Task/Organization Structure*

The experimental team decided to keep the subjects in the same position in the organization structure through all of the training and data runs; if a subject began the training runs as the CJTF for his team, for example, he would remain CJTF throughout the experiment. The only position for which this was not possible was the GCC/MCC position. Since half the experimental and training runs used a GCC, and the other half used an MCC, the individual who played this position would switch back and forth accordingly. This caused problems, as will be discussed in the lessons learned section of this chapter.

To the greatest degree possible, the experimenters and lead team attempted to match the subjects to positions in the organizational structure for which they had some operational experience. For instance, the MEUs were played by Marine and Army officers, and the CVBG and ARG were played by Navy pilots and surface warfare officers. Unfortunately, our sample was heavy in Navy officers, which meant that all of the MCC/GCC players were naval officers. This was not an issue when the intermediate level of hierarchy was an MCC, but caused difficulty when the intermediate level was a GCC. This will also be discussed in the lessons learned section.

**2. Operationalization of Task/Organization Structures**

The organization structures shown in Figure 4 and the task structures shown in Figures 6 through 9 were operationalized in three significant respects: through asset structure, communications structure, and information structure.

*a. Asset Structure*

The scenarios were designed so that if a unit must perform a specific task, then the assets required should be transferred to that unit, rather than the original owner attempting to perform the task for the unit that required the asset. For example, if MEU 2 was under attack by a tank column, the experimenters wanted MEU 1 to transfer the necessary asset (the Cobra helicopters) to MEU 2 to destroy the tanks, rather than MEU 1

destroy the tanks itself. This was done to ensure that the proper competition events actually occurred, and led to the issue of transferability.

All assets in the scenario were transferable, with few exceptions. The nontransferable assets included such assets as the amphibious shipping and the aircraft carrier, which were not directly needed to accomplish competitive tasks. All assets shown on Table 3 were transferable by their owners.

If the asset owner chose not to transfer an asset as requested by a unit needing it, a higher-level decisionmaker could force transfer of the asset(s). For example, if the ARG requested an asset from the CVBG, and the CVBG ignored the request, the MCC (if present) or CJTF could forcibly transfer the asset from the CVBG to the ARG, if he determined that the ARG's need for the asset outweighed that of the CVBG.

While all organic assets were owned by the lower level units (the MEUs, the ARG, or the CVBG), all non-organic assets were owned by the CJTF. No assets began the scenario under the ownership of the GCC or MCC. This was contrary to logic, because some non-organic assets were component specific, and should have naturally been under the control of the GCC or MCC, if present. An example is the SH-60 ASUW helicopters — if the MCC was present, he should have controlled the asset, because there is no conceivable use to which the ground component could have put the asset. If the MCC was not present in the structure, though, the asset would have been under the control of the CJTF. It was for this reason that all non-organic assets were kept under the control of the CJTF — the experimenters did not want the assets shifting back and forth between the CJTF and intermediate commanders for the different organization structures, but wanted to keep the asset structure constant.

#### ***b. Communications Structure***

Communications in this experiment were limited to preformatted messages using the DDD-III simulator. No verbal communications were allowed.

Copies of all messages sent by a decisionmaker were automatically forwarded to the next higher level in the hierarchy. If a lower-level unit, such as MEU 1, communicated with another low-level unit, such as MEU 2, a copy of the message was

sent to the intermediate commander. In this case, that is the GCC (if present) or the CJTF. And, if the intermediate level commander communicated with a lower level unit, a copy of his message was forwarded to the CJTF.

When an intermediate level commander was present, the low-level units could not communicate directly with the CJTF. In such cases communications followed the chain of command via the MCC or GCC, as the case may be.

### *c. Information Structure*

One of the major assumptions behind the "flattening" concept discussed earlier is the existence of a common operational picture (COP). All commanders at all levels must have a common view of the battlespace they must see the same threats, at the same time. Since our purpose was to test organizational structures in a future environment of shared, global information, the COP was one of the givens of our experiment. When one decisionmaker in the organization saw a threat or task, it was seen by all others at the same time. It was felt that this common view might reduce parochialism in certain circumstances, through fostering of shared mental models among team members.

## **3. Training**

The experimental team felt that the proper training of the subjects in the operation of the simulator and the requirements of the operations order (OPORDER) was vital to the success of the data runs. Two aspects of this training were significant: the training materials that the lead team and experimental team generated, and the conduct of the training itself.

### *a. Training Materials*

The lead team and experimental team developed three primary training aids for the training portion of the experiment: an OPORDER which transformed the scenarios developed by the lead team into a directive for execution of an operation, a tutorial designed to aid the subjects in using the DDD-III to implement the OPORDER, and the scenarios developed for the training portion of the experiment.

(1) Operations Order. When a military operation or exercise is conducted, an OPORDER is given as an implementation directive. This OPORDER tells the unit(s) that will conduct the operation or exercise the general situation, enemy forces, friendly forces available, the mission, how the mission will be executed, and logistics and command and control information. Since this was the language that the subjects spoke, the experiment team determined that the information that the subjects needed to execute the scenario should be given in that format.

(2) Tutorial. The tutorial was the link between the OPORDER and the DDD-III. It described the simulator to the subjects and its display and user interface, functions of the mouse, requesting, launching, moving and transferring assets, identifying and attacking threats, and use of communications messages. The tutorial also listed and described in detail all the objects that appear on the DDD-III screen, including friendly and enemy assets and terrain features, and gave a detailed description of the organization structures used in the experiment and how they are implemented in DDD-III. Finally, the tutorial included a single-page "cheat sheet" for use as a quick reference that concisely described all the objects on the screen and assets that must be used to destroy enemy threats, abbreviations used by DDD, and a list of assets, the platforms on which they are carried, and how each asset is used.

(3) Training Scenarios. The training scenarios, described in Section D of this chapter, were devised to help the subjects learn about the simulator and OPORDER, and allow them to become proficient in the skills that would enable them to compete over assets and successfully resolve the competition. The experimenters did not, however, want to "spoil" the competition events that would occur in the data runs, so the training scenarios had to be devised with care to not include competition events. These scenarios were written by the author, with advice and assistance from the lead and experimental teams. Refer to Section D for details of the scenarios that were developed.

***b. Conduct of Training***

Initially, the subjects were given a one-hour brief in a classroom on the fact that they were taking part in an experiment (no experimental objectives were included), the OPORDER, the organization structures they would be using, and the DDD-III. The purpose of this brief was only to give the subjects a general overview of what they would be doing during the training and experiment runs, and to give them some context for the training runs. The training runs were then conducted as previously mentioned, using the training scenarios which contained no competition events, but in aggregate, had a requirement for all of the subjects to use all the assets within each component. During the training runs, four members of the lead team were present to assist each team of subjects in familiarizing themselves with the simulator and OPORDER.

**4. Experiment Conduct**

The experiment took place during the weeks of 4-8 March and 11-15 March 1996. Two of the four teams were run through the experiment each week. Each team completed four training runs, followed by four trials during which data was collected (one for each task/organization structure combination), in a total of four two-hour sessions per team. The training runs and the data collection runs were each 40 minutes long, interrupted twice for situational awareness probes. In order to compensate for any learning effects, the data collection trials were counterbalanced so that each team encountered the four conditions in a different order, and each condition appeared in each place in the order exactly once, as shown in Figure 10. At least three members of the lead team were present at all times during the data collection runs, to monitor the subjects and collect data.

	Group A	Group B	Group C	Group D

<b>Session 4</b>	24MCC	13GCC	24GCC	13MCC

Figure 10. Counterbalancing of Trials for First A2C2 Experiment

## G. SUMMARY

The task design process described in Chapter III was implemented in this chapter to solve the task/scenario design problem for the initial A2C2 experiment. First, the experimental designers determined the task structure dimension of interest and desired structural characteristics of the task from previous research. Next, I iteratively developed scenarios using the task structure description paradigm generated in Chapter III that complied with the experimental designers' requirements. This was done within the constraints of the dimensions of task structure defined in Chapter II. Then, I graded the completed scenarios based on the grading scheme delineated in Chapters II and III, to ensure that the experimental objectives had been met. Finally, I described the experiment that was conducted using the scenario developed in this chapter, including further discussion of the operationalization of the scenarios and organization structures.

Chapter V will include a discussion of the lessons learned from the experiment with regard to scenario design, and from the above implementation of the scenario design process. It will conclude with a summary of the issues discussed in this thesis.

## **V. LESSONS LEARNED AND SUMMARY**

Upon completion of the experiment, based on the observations of the experimenters and the lead team, it was clear that there were some ways in which the experiment and the task design process discussed in this thesis could have been better implemented. I will focus here only on the items that are of specific interest to the task/organization structure and scenario development process.

Following discussion of lessons learned, I will provide a brief summary of the thesis.

### **A. LESSONS LEARNED FROM SCENARIO DEVELOPMENT PROCESS**

#### **1. Tradeoff Between Realism and Competition**

##### ***a. One-of-a-Kind Assets***

Several complaints were received from our more operationally astute subjects concerning the scenario's lack of realism. This was a difficult issue, and the experimenters struggled with it during scenario design. If the specific competition events of interest were to be induced in a consistent, repeatable manner, the scenario would have to force the use of one asset to perform a certain task. This is inherently unrealistic, since joint task forces commonly have several, or even many, different assets that could perform a given task. However, had we designed the scenario to more accurately reflect the real world, then the teams could have in essence created their own task structures, and avoided entirely the competition events that were the focus of the experiment. In retrospect, it would have been useful to make the competition involve a combination of assets, rather than a single asset. The tradeoff, though, is that that would have made scenario development much more complex, and would have increased the probability that operational background and "weaponeering" skill would have an undesirable effect on the variables of interest.

**b.     *Hard Prerequisites***

Designing the implementation of the scenario in the simulator so that certain activities must be performed before others can (hard prerequisites) is helpful for ensuring that a team follows a desired task structure. However, like the design of one-of-a-kind assets, development of hard prerequisites carries a price in terms of realism, and the value of strictly following a desired task structure must be weighed against the value of allowing a team to make mistakes or solve problems in its own way, and studying the team's mistakes or alternate paths.

**2.     Requirement of Modules to Describe Similar Missions**

As discussed in Chapter IV, each scenario was developed in two parts, a ground module and maritime module. It was desired that the tasks described in these modules be identical in dimensions of task structure and physical structure of the task *within scenarios*, because of the experimenters' desire to separate the modules for analysis purposes in order to double the number of data points — thus, Modules 1 and 3 would have to be identical, and Modules 2 and 4 would have to be identical. However, the nature of the missions of the ground component (amphibious assault — offensive in nature) and maritime component (support the amphibious assault — defensive and logistic in nature) were quite different. Although the dimensions of task structure and the task structure diagrams for each module were identical or nearly so within scenarios, this fundamental difference in the missions required a far different mindset on the part of the players for the conduct of each task, and negatively affected the experimenters' ability to consider modules identical within scenarios. It is my belief that, because of the difference in nature of air, land, and sea combat, and the parts each play in joint operations, this problem is not surmountable within the bounds of operational realism. Therefore, I believe that the modular approach to scenario development should either be abandoned or that *component* (land, sea, or air) be analyzed as a factor along with task and/or organization structure. Additionally, a further dimension of task structure could be added to the current list of nine: Nature of Mission or Nature of Task.

### **3. Span of Control Not Taxed**

There were not enough lower level units in the organization structures used for the CJTF to require an intermediate level commander. Since four people is not too many for an individual to supervise — his span of control was not taxed — he received no real benefit from the presence of an intermediate level of hierarchy. In fact, because the asset structure discussed above required that all non-organic assets be retained at the CJTF level rather than delegated to the intermediate commander (when present) to do with as he saw fit, the intermediate commander constituted a significant roadblock to mission performance when the JTF was competing over non-organic assets. Possible solutions would include increasing the number of lower level units in each component or increasing the number of components. The added units could come from either increasing the pool of subjects, requiring members of the lead team to function as confederates, or implementing additional units in software.

### **4. Additional Dimensions of Task Structure**

Based on lessons learned from the first A2C2 experiment, there are two additional dimensions, abstraction perspective and task significance, that an extension of the definitions of dimensions of task structure could incorporate for future experiments.

#### ***a. Abstraction Perspective***

Abstraction perspective refers to the context from which an activity is viewed. When a task is viewed from the highest level in an organization structure, the task may involve a different set of cognitive skills and activities than when it is viewed from the lowest level in an organization structure. For example, an amphibious assault, when viewed from the highest level in the hierarchy, involves such activities as planning, subtask decomposition and assignment, and resource allocation. When viewed from the lowest levels in the hierarchy, the task involves performing assigned subtasks, keeping superiors informed, requesting further orders/interpretations, et cetera. Representation in the task structure diagram of the perspective from which a task or subtask is viewed and

the activities that must be performed from that perspective would improve the development of task structures in future experiments. (Kemple, et al., 1996b)

***b. Task Significance***

Task significance was defined by Davis et al. (1991) as the value of the task output to the organization performing the task, and the interdependency between task outputs and other operations of the organization. I purposely left this out of the dimensions defined in Chapter II. However, it can be argued with some validity that the Modules 2 and 4 tasks (the maritime tasks) described in Chapter IV are less significant than the Modules 1 and 3 tasks (the ground tasks), since the ground objectives have priority, and this difference in task significance could confound analysis. Task significance should be accounted and controlled for in future experiments in order to address this issue. It would probably be best included in a Nature of Task dimension discussed in subsection 2 above.

**B. LESSONS LEARNED FROM CONDUCT OF THE EXPERIMENT**

**1. MCC/GCC Player Should Not Alternate**

The manner in which two organization structures were implemented, with the middle level of hierarchy alternating between GCC and MCC, was the source of some difficulty. First, the fact that one subject alternated between two positions, while all of the other subjects stayed in the same position throughout the experiment, meant that the GCC/MCC subject knew each of his positions less well than his teammates knew theirs. Second, in an actual JTF, the GCC or MCC could reasonably be expected to be a subject matter expert, and would probably be the senior ground or maritime officer in the JTF. That was not the case in this experiment. Since the same subject was both GCC and MCC, he had to be either a Navy officer or a ground officer. Because of the demographic makeup of the subject pool, the experimental team was forced to use exclusively Navy officers for the GCC/MCC position. While these officers had considerable expertise in maritime affairs, they were less expert on ground affairs than their subordinate MEU

since the decisions that these Navy officers could be expected to make while MCC would be based on a strong operational background, while those made while in the GCC position would not. A potentially alleviating solution would be to use different officers for the two positions, with a Navy officer as MCC and a ground officer as GCC.

Another option could be to change the organizational structures to: (1) CJTF with only lower level units and (2) CJTF with the same number of lower level units, but a component commander supervising each component. Although there are fewer subjects in the first structure than the second, that drawback could be outweighed by the ability to more clearly see the results of the flattened versus the hierarchical organizational structure through more general, whole-force performance measures, rather than measures directed specifically at one component. It would also allow for the GCC to only perform as the GCC, and the MCC as the MCC, and for each to be from a service which specializes in that type of action, and would better manipulate the CJTF's span of control.

## **2. Increase Time Pressure**

Additional time pressure would have improved the experiment. Two of the four teams operated under a reasonable amount of time pressure. The other two teams were composed of more operationally proficient members, and worked under relatively low time pressure. These two more operationally proficient teams tended to "max out" performance measures, making it difficult to find any difference between factor levels. A solution would have been to increase time pressure by increasing the simulator speed or increase the number of activities within each module.

## **3. Increased Number of Competition Events**

Each scenario module contained 3 or 4 competition events. It would have been useful to increase that to 5 or 6, or even more, to increase the number of data points.

## **4. Team Formation**

One difficulty encountered during the conduct of the experiment was the disparate levels of experience among the subjects. Those officers with significant operational

#### **4. Team Formation**

One difficulty encountered during the conduct of the experiment was the disparate levels of experience among the subjects. Those officers with significant operational experience and the "operational mindset" much more easily adapted themselves to the scenario than those without that experience or mindset, and tended to perform better. This extreme performance variability made it difficult to craft tasks that maintain a reasonably constant level of difficulty across teams and individuals. Possible solutions would be (1) make the scenarios less realistic and less operationally relevant, and more oriented toward abstracted decisionmaking, somewhat leveling the playing field, (2) additional training of teams, (3) exclusion of subjects without some relevant operational experience, or (4) finding some way to include the specialties of the non-operationally oriented in the scenarios. Of the solutions, (1) is not practical or desired. The direction of these A2C2 experiments should and will go toward more realism, not less, although at a higher level, as the experimenters attempt to gain insight into A2C2 in a joint operational-level context with more senior players. Solution (4) would be difficult, because of the variety of experiences of the non-operationally oriented. The lack of operational orientation was only a problem, in this case, with the Navy OCS officers. The Navy and Air Force do not have a real operational training baseline for many of their officers who do not attend a service academy or ROTC. If these officers are not in an operational specialty, then they tend to have little or no exposure to operational issues. This is not the case with Marine or, to a lesser extent, Army officers, who receive a common operational training baseline at various service schools. Implementing solution (4) in this case would have required that a job be found for a legal officer, an instructor at Nuclear Power School, and a communications officer, all with little or no knowledge of how the Navy fights, and this would have been very difficult to do. Solution (2) would also be difficult, because the amount of training required to bring a non-operationally experienced officer to the level of one with operational experience is not trivial. Solution (3), exclusion from the sample of Navy and Air Force officers without either operational experience or who had not attended a service academy or ROTC, is probably the most practical.

Officers who were operationally experienced, but played a role in the experiment outside of their area of expertise did not tend to function as well as their subordinates who were in their area of expertise. This was most specifically a problem, as was mentioned earlier, in the MCC/GCC realm. The fact that all the MCC/GCC players were Navy officers made judging the effect of the extra level of hierarchy more difficult, because the organizations tended to perform better when the middle level of hierarchy was on the maritime side, as would be expected when Navy officers were playing that role. The designers of future A2C2 experiments must ensure that great care is taken to match operational experience to the position played in the organizational structure, since those future experiments will likely see a *greater* level of operational fidelity, not less.

## **5. Training and Planning**

Some of the teams of subjects, particularly those with greater operational experience, approached the experiment as an exercise, in which they wanted to optimize their performance. These teams conducted their own "team" training prior to the data runs; they went over the OPORDER together, discussed its interpretation and implications, and formulated a plan within the plan that was provided to them in the scenario. Other teams did not do this, but approached the experiment in more of a "cookbook" fashion, in which the teams took the plan that was given them and executed it based on the training conducted by the lead team, doing no further coordination, planning, or training on their own. The scenario was designed assuming the subjects would take the second approach. It was thought that, if the subjects did much of the planning on their own, they would create their own task structures rather than follow the task structures that produced the competition events that the experimenters were interested in. However, this approach runs counter to realistic operational team performance, and to the aims of the overall A2C2 project.

The planning process would be a very likely time within the span of an operation for adaptation of organizational architectures to take place, because of the relative leisure, thoughtfulness, and potential for putting minds together to solve a problem in the planning environment, compared to the more hectic "crisis management" atmosphere that

prevails once the execution phase has begun. Additionally, commanders would probably be more willing to adapt the structure of their organization during the planning phase than they would during the execution phase. Alternatively, a planning phase (for the next portion of the operation) and the execution phase (for the current portion of the operation) could happen concurrently, or need to happen concurrently, which in and of itself could drive adaptation, in order to facilitate conduct of both phases simultaneously. For these reasons, not only should a planning phase be included in any future experiments and scenario (or concurrent planning and execution phases), but that phase should be a major focus of study.

### **C. SUMMARY OF THESIS**

This thesis was conducted as a part of the Adaptive Architectures for Command and Control (A2C2) project, which seeks to explore adaptation in command and control structures. The project's first experiment involves studying interaction between task structure and organization structure. This thesis described a process for developing military operational scenarios within a task structure context. First, I conducted a literature review, defined the dimensions of task structure applicable to this project, developed a grading scale for each dimension, gave examples of the dimensions and graded each example, and described how changes in one dimension might affect other dimensions. Then a method for developing scenarios in accordance with a predetermined structure and visualization of tasks was described, including a task structure diagram and a description of a task design process using the diagram and the dimensions previously delineated. I then applied the task design process by developing two scenarios for the first A2C2 experiment that differed across one of the dimensions of task structure, *coordination requirements*. Finally, I gave a description of the experiment, including discussion of operationalization of the scenarios and organization structures, and lessons learned from the experiment and application of the task design process with regard to scenario design.
